This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

STATE OF NEW YORK,

EXECUTIVE CHAMBER,

ALBANY, *April* 12, 1922.

To the Legislature:

I have the honor to present herewith the forty-second annual report of the State Commissioner of Health for the year 1921.

NATHAN L. MILLER.

NEW YORK STATE DEPARTMENT OF HEALTH

Commissioner, Hermann M. Biggs, M.D., LL.D.
Deputy Commissioner, Matthias Nicoll, Jr., M.D.
Secretary, Curtis E. Lakeman, A.M.
Executive Clerk, Fenimore D. Beagle

Directors of Divisions

Division of Sanitation	Charles A. Holmquist, C.E.
Division of Laboratories and Research	Augustus B. Wadsworth, M.D.
Division of Vital Statistics	Otto R. Eichel, M.D., F.S.S.
Division of Communicable Diseases	Edward S. Godfrey, Jr., M.D.
Division of Child Hygiene	Florence L. McKay, M.D.
Division of Public Health Education	B. R. Rickards, S.B.
Division of Tuberculosis	F. W. McSorley, M.D.
Division of Venereal Diseases	J. S. Lawrence, M.D.
Division of Public Health Nursing	Mathilde S. Kuhlman, R.N.

Public Health Council

Hermann M. Biggs, M.D., LL.D., New York City, *Chairman*

Mrs. Elmer Blair Chairman, Public Health Dept., General Federation of Women's Clubs	Albany
Simon Flexner, M.D., LL.D Director, Laboratories of Rockefeller Institute for Medical Research	New York City
Homer Folks, LL.D Secretary, State Charities Aid Association	Yonkers
Henry N. Ogden, C.E Professor, Sanitary Engineering, Cornell University	Ithaca
T. Mitchell Prudden, M.D., LL.D Vice-President, Board of Scientific Directors, Rockefeller Institute for Medical Research	New York City
Jacob Goldberg, M.D Ophthalmologist, Memorial Hospital	Buffalo

---

Consulting Staff

Bacteriologist	William H. Park, M.D. Director, Laboratories, New York City Dept. of Health
Animal Pathology	Theobald Smith, M.D. Director, Division of Animal Pathology, Rockefeller Institute for Medical Research
Communicable Disease	Alvah H. Doty, M.D. Former Health Officer of the Port of New York
Surgeon	George D. Stewart, M.D. Professor, Surgery, New York University and Bellevue Hospital Medical College
Dermatologist	Frederic C. Curtis, M.D. Former Professor, Dermatology, Albany Medical College
Pediatrician	L. Emmett Holt, M.D., LL.D. Professor, Diseases of Children, Columbia University, New York City
Child Hygiene	Henry L. K. Shaw, M.D. Former Director, Division of Child Hygiene, State Department of Health
Statistician	Walter F. Willcox, Ph.D Professor, Political Economy and Statistics, Cornell University
Public Health Education	C.-E. A. Winslow, S.B., Dr. P. H. Professor, Public Health, Yale University
Orthopedic Surgeon	Robert W. Lovett, M.D. Professor, Orthopedic Surgery, Harvard University
Orthopedic Surgeon	Royal Whitman, M.D. Attending Surgeon, Hospital for Ruptured and Crippled, New York City
Syphilographer	John A. Fordyce, M.D. Professor, Dermatology and Syphilis, New York College of Physicians and Surgeons

FORTY-SECOND ANNUAL REPORT OF THE STATE DEPARTMENT OF HEALTH

REPORT OF THE COMMISSIONER OF HEALTH

Letter of Transmittal

To the Honorable NATHAN L. MILLER, *Governor of the State of New York, Albany, N. Y.:*

SIR.— I have the honor to submit herewith the forty-second annual report of the State Department of Health.

In the reports of the several Divisions of the Department will be found a comprehensive and detailed account of its activities during the year 1921. In commenting on the salient features of the work of the Department as thus presented, I desire further to call attention to some of the existing problems and needs of the health administration of the State.

The Public Health Council

The report of the Public Health Council has already been transmitted to you. As the administrative head of the Department, I should like to direct attention to the unusual character of that report, which has been prepared entirely by my colleagues on the Council, and which takes the form of a review of the public health administration of the State since 1914. On behalf of the executive staff and personnel of the Department, I desire to express sincere appreciation of the terms in which the Council has described the activities and accomplishments of the past 8 years of effort to improve the health of the State.

The Health of the State in 1921 *

The year 1921 was marked by the lowest general death rate and the lowest infant mortality rate in the history of the State. The death rate from all causes for the year for the entire State was 12.3 per 1,000 population, as compared with a rate of 13.8 for the year 1920, and of 15.1 for 1914, the year that the State Department of Health began to function in its present reorganized form. In terms of lives saved, this means that approximately 16,000 more people of the State are now living than would have been the case if the 1920 death rate had not declined in 1921.

It further appears that the death rate for the State exclusive of New York city in 1921 was 13.7 per 1,000 population. The rate in the up-state cities was 12.6, as against 14.0 for the rural districts.

---

* Some of the rates in this section differ slightly from those contained in the original report submitted by the Council as they were provisional only; in this printed report the final figures have been substituted which differ only slightly from the provisional figures.

Although the crude death rate of New York city for the year was below that of the rest of the State, if these rates were corrected by adjusting them to a standard population in order to eliminate the effects of differences in age distribution, the New York city rate would be slightly higher than the up-state rate. In other words if allowance is made for the greater proportion of older people in the up-state population, it will be found that the 1921 rate was really lower up-state than in New York city. These standardized rates cannot be computed for 1921 as all the data required are not available at this time. Rates prepared for 1920 show the relative difference,— in that year the crude rate of New York city was 12.9 and of the rest of the State 14.9, but the standardized rates were 14.0 and 13.0 respectively.

The Reduction of Tuberculosis

The most remarkable feature of the year's health record was the unparalleled fall in the mortality from pulmonary tuberculosis. The 1921 death rate from this disease reached the unprecedently low figure of 89.2 per 100,000 population, as compared with 105.5 for 1920, previous to which year it was even higher. This is equivalent to the saving of 1,719 lives from this one disease alone. While the universal and highly developed campaign waged against tuberculosis for many years by public and private agencies has undoubtedly contributed materially, the drop in the death rate from this disease is so considerable that it is difficult to find a complete explanation for a phenomenon so gratifying.

The usual activities of the Department in this field were carried on during 1921. Following the established policy which has also given excellent results in the aftercare of poliomyelitis and in other child hygiene work, the cooperation of local physicians has been secured in holding 54 tuberculosis consultation clinics in 19 counties, practically all of them in rural districts where tuberculosis dispensaries, the x-ray and other modern aids to diagnosis were not available. Over 1,600 patients were thus examined during the year, and 1387 radiographs taken with a portable x-ray outfit, to be developed later at headquarters, after which the results were reported to the local physicians. This work, besides the inspection of 37 county and city tuberculosis hospitals, and the inspection of sites and plans for new institutions, was carried on by a departmental staff which includes only 2 physicians.

In view of the great interest in child health at the present time it is of interest to note that 42 per cent of the patients examined at clinics held by the Division of Tuberculosis were 15 years of age or under. Besides the heart and lung examinations and x-ray, the eyes, ears, nose, teeth, tonsils and general condition were investigated and treatment suggested.

Other Communicable Diseases

Except for a marked outbreak of poliomyelitis, there were no serious epidemics during the year. More cases of that disease were reported than in any year of record except 1916 and 1912.

The epidemic of 1921 began in July and was centered in the city of Utica and adjoining parts of Oneida county, which reported over 35 per cent of the total of 561 cases occurring during the year outside of New York city. Fortunately the severity of the disease and the percentage of deaths were not as great as in the memorable epidemic of 1916.

The typhoid fever rate, although very low, showed a slight increase over 1920, following a long period of steady decline that has extended over many years. A considerable number of important local outbreaks in 1921 were traced to infected milk, due to typhoid carriers or to active cases of the disease. In none of these instances was the milk pasteurized. The prevalence of typhoid seems to have been occasioned in part by abnormally dry summer weather which in many cases brought about a temporary resort to doubtful private sources of water supply, especially in rural districts, when the normal sources failed.

Smallpox also was more prevalent in 1921 than in 1920. All of the outbreaks occurred in the smaller communities, where vaccination is not usually practiced until a definite outbreak arouses local sentiment. In the 9 largest cities of the State where vaccination is required as a condition of school attendance, no outbreaks of smallpox occurred and the rate for the disease for those cities was only 1-13 of that elsewhere in the State.

Toward the end of the year unmistakable evidence accumulated of the prevalence in several counties of epidemic jaundice, a disease which has rarely been reported in this State. Investigations were at once instituted to ascertain whether this disease is identical with the epidemic jaundice of Japan, the causative organism of which has been found in rats and mice. The first outbreak of the year was reported from Chenango county, where an epidemic of hiccough attracted attention and led to further investigation. The symptoms reported in this outbreak correspond to the description of epidemic jaundice as it has occurred abroad, and occasionally in this country in the past. Investigations by the field and laboratory forces were promptly undertaken in order to establish the identity of the disease and to determine the method for its control. Rats and mice are suspected of having much to do with its spread, which furnishes an additional reason for the ruthless destruction of these pests.

Child Health Consultation Serivce

A " healthmobile " traveling unit, consisting of a physician, a nurse, and an advance agent, has visited 108 small rural communities during the year, and examined 5,126 children in 20 counties, instructing these children and their mothers in measures for the improvement of their health. During the winter months similar consultation clinics were held in places of 2,000 to 5,000 population accessible by railroad, and in fifty such consultations 2,335 additional children were examined, making a total of 7,461. Moreover, as a direct result of these departmental consultations local agencies have been stimulated to organize similar work in 11 counties, whereby 1,862 more children in rural districts have been examined, making a grand total of almost 10,000. No treatment is given at any of these consultations but each child needing medical care is directed to his family physician, to whom the Department sends the record of the examination. It is estimated that at least 50 per cent of the children examined have already had their defects corrected or are under treatment.

Child Hygiene Stations

There are now in existence in the State 134 child hygiene stations in 76 municipalities, which are caring for approximately 20,000 infants, 5,500 preschool children and 1,600 prenatal cases. Sixteen of these child hygiene stations have been established during 1921 as the more or less direct result of the children's health consultations held by the Division of Maternity, Infancy and Child Hygiene.

Aftercare of Infantile Paralysis

Since the 1916 epidemic of poliomyelitis, special appropriations have enabled the Department to carry on a system of consultation clinics for the purpose of giving expert advice to local physicians and nurses in the care of crippled children, and to insure the provision of the necessary orthopedic appliances. The outbreak of this disease in 1921 materially increased the needs and the number of cases of this kind, of which 1,498 were under observation at the end of the year. Sixty-seven clinics were held during the year and 919 patients were examined.

Rural Medical Service

It is in these branches of its work that the Department has occasion to appreciate the pressing need in the rural districts of the State, for better medical service — for more physicians, more hospitals, more laboratories, and more diagnostic clinics to bring the practical benefits of modern science to the children and to the adult population of the sparsely settled portions of our State. Under present conditions the number of physicians in rural districts is rapidly decreasing. This subject, which has had the attention of the Department for some years, is discussed in the report of the Public Health Council. Whatever the remedy finally determined upon, it is a problem which presses for early solution.

Venereal Diseases

In spite of the reduction in available funds, and the consequent reorganization and consolidation of the staff, this division has lost none of its headway, and has made noteworthy progress in its efforts to teach the public that syphilis, gonorrhea and chancroid are dangerous communicable diseases which destroy the health and jeopardize the lives of those infected. Although it has been necessary to discontinue the manufacture and distribution of arsphenamine (salvarsan) by the Division of Laboratories, the emphasis on educational work has made possible the reaching of over 100,000 people by hundreds of lectures in 26 counties, while more than 320,000 educational pamphlets have been mailed and over 1,000 posters distributed. Three years ago there were but 3 venereal disease clinics in the State outside of New York city; now there are public clinics in 36 cities, largely established through the efforts of the Department.

Public Health Nursing

The 28 nurses of the Department, grouped for administrative purposes in the Division of Public Health Nursing are detailed for field duty to the other divisions and have assisted during the past year in the control of communicable diseases, in tuberculosis, child hygiene, and venereal disease clinics, in the supervision of midwives, in the aftercare of infantile paralysis patients, in the prevention of blindness, in securing registration of births, and in many other essential activities of the Department. Institutes for public health nurses were conducted in New York, Syracuse, and Albany, and many lectures were given before various nursing groups.

Public Health Education

In addition to the specific educational work carried on by several of the other divisions, the Division of Public Health Education has continued to publish the three monthly bulletins of the Department, to issue occasional statements to the newspapers, and to edit and distribute special circulars and pamphlets. In 1921 approximately 450,000 pieces of printed matter were sent out, many lectures were arranged and speakers furnished, and the effective field work of the Healthmobile unit continued in rural districts. Eighteen motion picture films were shown 213 times to a total of approximately 144,000 people. A new film showing in detail how the farm house may be equipped with modern plumbing is especially popular. Lantern slide lectures and health films are demonstrably more effective and economical methods of health education than exhibits of panels and models.

Laboratory Service

During the year certain economies and consolidations have been effected in the laboratory work of the Department, but with no loss of efficiency. It may not be generally realized that the development of the central laboratory in Albany and its branch in New York city, in cooperation with over ninety approved local laboratories, has set a standard and provided the citizens of the State with the best equipped and administered public health laboratory service in the world. In 1921 these laboratories performed the enormous total of 1,183,938 examinations of specimens. Nevertheless, there is yet much to be done in the way of new construction to provide adequate space for the present work of the central laboratory in Albany and in the development of local laboratories and supply stations in the rural districts. Cooperation with local health officers especially has made substantial progress during the year. Members of the staff have assisted in 12 courses of instruction in public health. Several notable studies have been published during the year, and various procedures improved as the result of researches.

Sanitation

By legislative enactments which became effective July 1, 1921, the duty of passing on plans for sewerage systems and waste disposal plants was transferred to the office of the State Engineer. As a result, the reorganized Division of Sanitation is carrying on the remaining functions of the Department in the field of sanitary engineering with less than half the former number of employees. Meanwhile the volume of routine work was increased by the dry summer, calling for the safeguarding of many auxiliary sources of water supply. Practically all demands of this character were met, however, and not a single outbreak of typhoid during the year could be attributed to polluted public water supplies.

Vital Statistics

The usual high standards of complete registration of births, marriages, and deaths, were maintained throughout the year,— which was made possible partly through the effective cooperation of the local registrars. The publication of the annual statistical reports for 1918 and 1919 was delayed because of the influenza epidemics and accidents, but these volumes will appear during 1922. The report for 1918 is now being printed and bound and preparation of the subsequent volumes is proceeding according to schedule.

For the first time in the history of the State special tables of marriage statistics have been prepared and are now in press. Also a special compilation of descriptive statistics of the 1918 influenza epidemic was prepared and is also in press. An elaborate tabulation of the infant mortality data of the State was undertaken and is now being printed as a special report. Many of the tables of marriage and infant mortality data will henceforth appear with the standard tables in the annual reports.

The Division cooperated with the New York State College for Teachers by receiving some of its students in mathematics and statistics for practical training by laboratory methods, an arrangement which was of mutual benefit.

During the year many analyses were made for the administrative use of the Department, which were not, however, of sufficient general interest to warrant their publication. This statistical service of the Division has been steadily developed as a feature of its practical work, but its continuance or further extension is, of course, dependent upon the personnel and other resources which may be available.

General Administration

During the year 1921, nineteen new consolidated health districts were set up, making a total of 132 such districts in the State at the end of the year. Including these, there are now 1,466 health districts in the State outside Greater New York, represented by 969 health officers.

A total of 924 municipalities have now adopted the Sanitary Code regulations based on the model code prepared and recommended by the Public Health Council.

The annual conference of the Department with the municipal health officers of the State was held at Ithaca on September 13, 14 and 15, 1921, and was unusually successful, the attendance reaching a total of 928. These conferences have become an established annual institution, and their contribution to the raising of the standards of the public health work of the State is unquestioned.

Courses for health officers have been held during the year at the University of Syracuse, Albany Medical College, University of Buffalo, and New York University. An additional course was held in 1921 in the city of Ithaca, reaching a number of health officers in that vicinity. The total number of health officers who have completed the approved courses since they were introduced by the Public Health Council is 430.

The fifteen Sanitary Supervisors of the Department have continued their effective work in supervising and stimulating public health activities in their several districts. During the year 1921 the Sanitary Supervisors conducted or assisted at 469 clinics, of which 295 were devoted to child welfare and 76 to tuberculosis, the remainder of 98 being of a miscellaneous character.

Legislation

A long step forward in local health administration was made possible by the enactment of chapter 249 of the Laws of 1921, which permits any second or third class city to abolish its board of health and substitute a single, responsible health officer, accountable for his acts directly to the mayor or other supreme appointive authority. This is in accord with accepted modern views of the best principles of municipal administration, as well as in line with the organization plan under which the State Health Department has been able to accomplish so much since 1914. Under this permissive act, the city may fix the term of the health officer at four years, and thereby measurably counteract the possibility of unwholesome political influence. The removal of several excellent health officers after the city elections of 1921, apparently on political grounds, emphasizes the need of establishing municipal health services upon the sole basis of competence and character. The law should be strengthened by making it impossible to remove the health officer except upon charges, sustained after a public hearing, by proof of incompetence or serious misconduct. There is no good reason why a competent health officer should not be permitted to serve his community as long as he is physically and mentally able to do so. Politics should no more enter into the selection and retention of the health officer by a community than it now affects the individual citizen's choice of his private physician.

There is little else in the way of new legislation which the Department has occasion to recommend at the present time. Experience indicates, however, that steps should be taken to expedite the procedure for the prosecution of violations of the public health law and the sanitary code, especially in rural districts. At present it is necessary to hold such violations for action by the grand jury of the County or Supreme Court. Legislation conferring on courts of special sessions or police justices sitting at such courts, jurisdiction in the first instance to hear and determine charges of misdemeanor in violation of the health laws would eliminate delay and effectively promote the adequate enforcement of the law.

Budget Control

I trust it may not be out of place to express the keen satisfaction which the Department derives from its experience with the new state system of budget estimates and appropriations, as administered by the Board of Estimate and Control. The survey of the work of all divisions of the Department of Health made under the competent direction of the Board has resulted not only in findings and detailed recommendations of very definite value in the improvement of the service, but has, in my opinion, had the most salutary general effect of bringing about closer contact and better understanding between the officials of the Department and the Governor and Legislature.

No more progressive step has marked the financial administration of the Department than the plan of grouping personnel appropriations, which was applied by the Legislature to the Division of Laboratories this year. While retaining a full measure of supervisory control in the appropriation bill, the plan still bestows a degree of flexibility in administration that makes possible the meeting of varying conditions in the service and the effecting of concrete economies, while at the same time permitting the more equitable adjustment of compensation within the established limits. This has undoubtedly increased the contentment and efficiency of the personnel, and thereby advanced the quality and quantity of service output. It is earnestly hoped that the plan may be applied to other divisions of the Department in the next annual budget.

I cannot close this report without referring with regret to the very cramped office quarters in which the Department is now compelled to do its work. With the increase of staff already seen to be inevitable in 1922 the solution of this problem will become a matter of the first importance. It is physically impossible to provide for certain foreseen expansions in the present quarters in the Capitol, while the difficulty of securing office space elsewhere in the city is well known.

Respectfully submitted
HERMANN M. BIGGS
March 1, 1922 *Commissioner of Health*

PUBLIC HEALTH COUNCIL

PUBLIC HEALTH COUNCIL

His Excellency, Nathan L. Miller, *Governor of the State of New York, Albany, New York:*

Sir.— The Public Health Council of the State Department of Health finds it necessary, for the adequate performance of its duties, to keep itself informed about the wide range of practical activities of the Department; since concerning these as well as the outlooks for more effective public service, the members of the Council are in frequent formal and informal conference with the Commissioner and the Deputy Commissioner of Health. The Council's survey of the activities of the Department this year has been more than usually retrospective, and has shown so striking and gratifying a record that, though the Council has been directly concerned with but a few of these great administrative achievements of this last decade, we venture to call the attention of your Excellency to them as a sketch of the background in which the Council as well as the active workers in the Department find inspiration, and the leaders, direction and control for future plans.

A Retrospect

The Public Health Law of the State of New York was revised in 1913 in accordance with the recommendations of a commission which made an extensive study of the existing conditions. The present Commissioner of Health was the chairman of this commission. At that time the State Department of Health had very limited facilities, was, in fact, chiefly a paper organization — excepting the Division of Engineering and the Division of Vital Statistics. In 1914 the reorganization of the Department was effected. Some glimpses of the changes and improvements in the condition of the public health and in public health administration in the State and elsewhere since that time are here brought together in review, marking as they do the results of the activities of the reorganized State Department of Health, cooperating with the local health officers, the State Charities Aid Association, and other official and voluntary agencies.

(1) **Administration.**— 1. Several provisions of the revised public health laws have been so highly regarded by sanitarians and public health officials that they have been incorporated in the public health laws of several other states.

2. The Public Health Council has enacted a Sanitary Code having state-wide effect, which it endeavors to hold abreast of the advances of science and adapted to the changing neds of the community. It has also prepared a model local Sanitary Code which has been adopted by over 800 local municipalities, thus fostering a uniform plan of local health administration throughout the State.

3. The number of local health officers has been reduced through

consolidation of health districts and the efficiency of administration and the compensation of the health officers have thus been correspondingly increased. While originally there were 1466 health districts and health officers in the State outside of New York city, today we have 1329 districts served by 966 health officers.

4. Branch offices have been established in the cities of New York, Buffalo, Syracuse and Hornell; also a branch laboratory has been established in New York city.

5. In 1913 there were less than 100 public health nurses employed in the State outside of New York city. There are now over 1150.

6. Nurses have been supplied to the Indian Reservations and to the child hygiene, tuberculosis, venereal diseases and group-consultation clinics.

7. In 1913, 87,829 pieces of first class mail were received; in 1920, 204,498 were received — an increase of 133 per cent. In 1913 a total of 196,445 pieces of mail were sent out; in 1920, 791,516 pieces of mail were shipped — an increase of 303 per cent. The total number of pieces of supplies and literature sent out during 1920 was 2,290,692.

(2) **Vital Statistics.**— 8. The reorganized Department has perfected the registration of vital statistics so that the registration of births and deaths is now practically complete, and the fullness, scope and value of the reports of communicable disease have been very greatly improved. No more reliable statistical data are now available in the United States than in the State of New York, and none are more instructively presented.

9. The general death rate for the State, exclusive of New York city, has declined from over 15 and a fraction per 1,000 population to less than 14. Each point reduction in the general death rate equals about 5,000 deaths.

10 The general death rate for 1921 — 13.5 per 1,000 of the population — was the lowest in the history of the State.

11. The death rate from pulmonary tuberculosis has been greatly reduced. In 1910 it was 124.1 per 100,000; in 1921 it was 86.2 per 100,000.

12. The infant mortality of 1910 was 135 per 1,000 births; for 1921 the rate was 81.

13. The death rate from typhoid fever in 1910 was 18.7 per 100,000; in 1921 it was 5.3.

(3) **Laboratory Service.**— 14. It has set a new standard to the world in the development of public health laboratory service for a state, and in the organization and standardization of all the county, municipal and private laboratories of the state engaged in public health work; so that they can cooperate with the large and well-equipped central laboratory in Albany as a unit.

15. It performed in its laboratories 201,531 diagnostic examinations last year.

16. It distributed last year 190,965 outfits for specimens for bacteriological diagnosis.

17. It produced and distributed in 1920, 148,217 packages of serum and vaccine for the treatment and prevention of infectious diseases.

18. It produced and distributed over 70,000 doses of arsphenamine for the treatment of syphilis.

19. It has stimulated the establishment of municipal and county public health laboratories and has supervised and standardized their work. There are now over 90 approved local, municipal and county public health laboratories subject to inspection.

20. Nearly 400,000 diagnostic examinations were made in these approved laboratories in 1920.

21. Local municipal laboratories have been established in epidemic emergencies. In several instances these have been subsequently taken over and maintained by the local authorities.

22. In emergencies the work of local laboratories has been supplemented by the mobile laboratory units.

23. It has established throughout the State depots for the distribution of laboratory products — serums and vaccines for the treatment and prevention of disease — where these as well as outfits for the collection of specimens for diagnosis can be readily obtained by practicing physicians.

24. The New York State Association of Public Health Laboratories — an independent organization — has been formed to stimulate and coordinate the work of the local laboratories. There are semi-annual meetings, one of which is held at the State laboratory in Albany.

25. The State laboratory furnishes training for laboratory technicians, bacteriologists, serologists and directors of local laboratories, thus ensuring an available personnel, otherwise unobtainable.

(4) **Education.**— 26. The Public Health Council has established minimum qualifications for health officers, and through the public-spirited cooperation of teachers and colleges, courses of training have been provided in New York, Albany, Syracuse and Buffalo, which more than 600 health officers have either taken or are now taking.

27. Intensive courses of training for nurses have been provided and are now being conducted, at which public health nurses have been given an opportunity to qualify themselves for their work.

28. Annual conferences for health officers and public health nurses (which have been extraordinarily helpful and successful) have been held. The average annual attendance has been from 800 to 900.

29. The Department has held under the direction of its Sanitary Supervisors once or twice annually in each sanitary district a conference for local health officers and public health nurses.

30. It edits and distributes four monthly publications — Health News, Public Health Nurses' Bulletin, Health Officers' Bulletin and Vital Statistics Review.

31. It has prepared and distributed manuals for health officers and public health nurses.

32. It has carried on through the press and in other ways continuously a general educational campaign on public health.

33. It has carried on extensive educational campaigns in many cities of the State on venereal diseases, tuberculosis, child welfare and diseases of adult life.

34. It has for a number of years conducted educational exhibits in public health in connection with the State Fair at Syracuse and with the county fairs throughout the State.

35. It is constantly providing lecturers on various public health topics for organizations of various kinds such as Farm Bureaus, Home Bureaus, Y. M. C. A. and Y. W. C. A. organizations, factory employees, women's clubs, etc.

36. In the past three years more than 1,500 lectures have been given before about 250,000 people.

37. In 1920 more than 100,000 persons were addressed by the lecturers on venereal disease.

38. It is estimated that the Division of Venereal Disease exhibits have been seen by over one million people.

39. Circulars and pamphlets of information regarding venereal disease, numbering about two and a half million, have been distributed.

40. More than 40,000 venereal disease posters have been placed.

41. The Department has kept in circulation 34 moving pictures films; one alone of these during six months was shown to 15,570 people.

42. In cooperation with the Farm Bureaus, it has assisted in organizing and addressing 175 classes in the home care of the sick, which reached 12,865 women.

43. It has brought about the organization of health centers in a number of cities of the State.

(5) **Child Hygiene.**— 44. In 1913, outside of New York city there were 32 child hygiene stations in 12 municipalities of the State; these were increased to 67 in 32 localities in 1914 and further increased to 95 in 52 localities in 1920. The work of these increased from 11,680 infants under care during 1914, to 31,311 children (27,156 infants and 4,055 children of pre-school age) under care during 1920; while in addition there were 1,792 mothers under care during the pre-natal period.

45. During 1920 there were conducted in these child hygiene stations 3,315 clinics; and 79,343 home visits were made to these little patients by the clinic nurses.

46. A Healthmobile, especially designed and equipped for rural medical clinics, was utilized during 1920 for the examination of 2,722 children for remedial physical ailments. At similar consultation clinics held during the present year (1921) 8,244 children were examined; making to date a total of about 11,000. Not included with these are many other similar consultations held under local supervision in cooperation with officers of the State Department. Through the cooperation of local public health nurses and health officers, subsequent oversight has been main-

tained over children found with physical ailments or defects, and an effort is made to secure and foster the treatment of ailments and the correction of defects by the family physician.

47. The Department supervises and inspects the activities of 52 day nurseries.

48. Before 1914 there was little or no supervision of midwives in this State outside of the cities of New York and Buffalo. Today there are 616 midwives licensed by the State Department of Health, and under its constant supervision by its own supervising nurses with local public health nurses working in cooperation with them.

49. The Department has supervised the aftercare of more than 2,500 cases of infantile paralysis scattered throughout the State remaining from the 1916 epidemic, and in addition to these has taken over the supervision of many other cases from previous outbreaks of this disease. This work has been of surpassing value in rescuing these pitiful victims of disease from the miseries and handicaps of incurable cripples.

(6) **Communicable Diseases.**— 50. The Department is constantly aiding local authorities in the suppression of outbreaks of various forms of communicable disease, both by furnishing epidemiologists and nurses, and in laboratory service.

51. It annually receives, tabulates and analyzes over 150,000 reports of cases of communicable disease.

52. It has conducted tuberculosis surveys in connection with the local authorities in many counties of the State.

53. In 1910 there were only 650 beds available for tuberculosis in the State outside of New York city. There are now in 40 counties, having a population of 35,000 or more, 37 county hospitals and 7 semi-charitable institutions for tuberculosis with an available bed capacity of 3,827.

54. It has provided model plans for county tuberculosis hospitals of different capacities and has inspected and passed on the sites and the water supplies and building plans of these institutions, and advised the county authorities in their erection, and in any subsequent additions or extensions.

55. It has brought about the establishment of tuberculosis clinics in 38 cities and 6 of the larger villages in the State.

56. In 1920, 73 tuberculosis clinics were conducted in 32 counties and 2,363 patients were examined. Previous to 1920, 306 clinics had been held in 37 counties, and 6,282 patients examined

57. Modern clinical facilities for diagnosis are provided by the Department for local health officers and physicians. During the present year 2,400 X-ray pictures were made of doubtful cases presented for diagnosis.

58. The activities in the prevention and control of communicable diseases are conducted directly through the activity of Sanitary Supervisors who made over 500 visits during 1920 on account of communicable diseases alone and directed the measures employed in controlling nearly 100 local outbreaks.

59. The Department has brought about the establishment of venereal disease clinics in 36 cities of the State.

60. It has applied the Wassermann test to the inmates of all voluntary and public institutions for children to which admission could be obtained. More than 10,000 examinations have been made.

61. Largely as a result of stimulation by the Venereal Disease Division the Wassermann test has been applied to the inmates of the State prisons and to most of the inmates of the state hospitals.

62. It has conducted in the cities and rural sections of the State a number of general diagnostic clinics where experts in the various departments of medicine have given free consultation to physicians in the diagnosis and treatment of obscure cases of disease.

(7) **Sanitation.**— 63. The Department has conducted, under special orders of the Governor, extensive examinations — such as those regarding oil pollution of the waters of New York harbor and the nuisances arising from the operation of the industrial plants at Edgewater in relation to the Riverside Drive section of New York city.

64. It has inspected 550 watersheds and public water supplies of the State, reported on the conditions found, made recommendations as to improvements which should be made, and kept them under supervision and reinspected many of them.

65. It has supervised the operation of a very large number of sewage disposal plants.

66. It has made extensive surveys of the oyster beds of Long Island and Staten Island with reference to pollution by sewage.

67. It is constantly conferring and advising with the local authorities in all parts of the State on sanitary questions of every variety.

68. During the drought of the summer in 1921 the Division of Sanitation was called upon repeatedly to assist municipalities in installing emergency chlorinating plants for sterilization of auxiliary water supplies to augment the regular supplies which had become inadequate. Its emergency plant was in constant use and in many cases emergency treatment plants were installed.

69. The Department has prepared permits for the discharge of sewage and sewage effluent in the waters of the State.

70. It inspects as to construction and sanitary condition, and supervises the operation of nearly 300 milk pasteurizing plants supplying pasteurized milk to the cities of the State excepting New York city.

71. It has inspected and brought about the abolition of thousands of public nuisances having local or general effect.

72. It has made sanitary inspections and reinspections of all the state institutions.

Such are the activities of this Department of Health, in which the interest of the Council centers, as befits that advisory body, before which are brought for discussion and advice new projects for the improvement of the public health, questions of emergency administration, problems in which the technical knowledge and experience of its members may be helpful, suggestions for making the provisions of the Sanitary Code more effective and less burdensome to the community. And the Council may venture here to express to your Excellency, with less reserve than would be natural to the Commissioner under whose wise guidance these triumphant achievements in welfare have been secured, their pride and satisfaction in the privilege of sharing in so excellent and fruitful a public service.

The Local Health Officer

When the Public Health Council was created, it was specifically charged with the task of advising the Commissioner as to methods by which a higher standard of public health might be maintained throughout the State. The crude death rates of the 24 states included at that time in the United States Registration Reports show New York to be the eighteenth on the list, apparently considered a dishonorable place for the Empire State.

The legislators, or those responsible for the Public Health Law of 1913, evidently acting with prophetic vision of better standards of living, by the very fact of its creation made the Public Health Council its agent for securing both a greater exemption from particular diseases and a larger enjoyment of unalloyed good health.

In studying the problem the Council were soon persuaded that the matter was one in large measure of education, that while in general it was well known, for example, that diphtheria was both preventable and curable, it was evident that in parts of the State medical practice failed to avail itself of the proper preventive and therapeutic agents or that in many sections of the State individuals, if not entire communities, were so isolated as to be entirely dependent on the knowledge and skill of their local medical practitioner, who in many instances had no experience in the use of the new treatment by vaccines and antitoxins. To the self-sacrificing devotion of these men, often advanced in years, who at the call of the sick traveled and still travel over miles of rough mountain road, in all kinds of weather, no tribute of appreciation can be overstated. The physical hardships incident to such devotion to duty has shortened the days of many a country practitioner and many lives have been offered as sacrifices to those they served.

The insistent demands of their practice continually renewed gave little time for reading and study, and in many a doctor's office could and doubtless can yet be found piles of medical journals, crowded with the latest discoveries of medicine and their applications, thrown into a corner unopened because of more pressing calls. Men of such training when appointed health officer were loyal and earnest agents of the Department in so far as they had time, and to the extent of the knowledge given them in the medical schools of the 70's and 80's. But modern medicine may almost be said to date from that time; the advances and changes of the last 30 years are staggering — so violent has been the upheaval of the old theories and methods. As an example, pneumonia, then was an inflammation of the lungs, to be treated in an air-tight, overheated room by external applications to the chest. Now the treatment, among other things, is free exposure to outdoor air and nourishing food.

The problem of giving to such isolated health officers the opportunity of again coming abreast of most recent theories, particularly of communicable diseases, was easily seen to be complicated by the very small financial return attached to the position of health officer. The Council found many cases where the compensation was less than $100 a year, even after the legal payment of 10 cents per capita was observed; a sum obviously too small to justify the recipient in spending any large sum and much time in qualifying preparation. One hundred and ninety-four towns of the State have each a population of less than 1,000 — *i. e.*, the health officers of those towns have salaries almost negligible. Some advantages in administration have accrued by the consolidation of the smaller districts, 1,466 health districts having been reduced to 1,329 districts by this means, and the compensation provided by the larger district thus correspondingly increased. But there are even yet a very large number of towns in which the health officer receives only a nominal salary. No special university training could be expected when the reward was so meagre, and the fact that then, even in cities, there were few full-time health officers and all health officer salaries, part time as well as full time, inadequate, made the problem one difficult of any general solution.

After long consideration, the Council invited the several medical schools of the State to take the problem as outlined above under advisement with a view of furnishing opportunities to those willing to avail themselves, and finally four schools, viz., University of the City of New York, Syracuse University, Albany Medical School and University of Buffalo, arranged courses that were published as open to practicing physicians. These courses were of several kinds, either (1) correspondence courses, in which the work consisted of questions to be answered by reference to the latest books on sanitation and a week's laboratory practice; or (2) by a day and a half lecture and laboratory session on each of six successive weeks; or (3) by actual continuous residence for ten days. It was hoped that the interests of their profession, if not the success of their administration, would induce many physicians to renew their studies and thereby react as physicians on their patients and as health officers on their communities. As a further inducement the Council enacted, in fixing the qualifications for appointment, that every health officer appointed after 1915 must have received a certificate from a medical school to the effect that the appointee had successfully pursued a special course in sanitation and public health, duly approved by the Council.

The Department of Health itself cooperated in every way possible in this campaign, allowing the officers to give lectures, opening the laboratories as needed, giving advice on courses, material and texts, and even acting as registrar, to relieve one of the schools of the extra clerical work. The response of the health officers and the effect on the public health work of the State has been equally gratifying. At the present time more than half of the health officers now in office have temporarily absented themselves from their practice for the sake of the self-improvement made possible by the cooperation of the schools. The practical methods of modern serum therapy have been appreciated and put into practice. Never was the control of communicable disease throughout the State so complete or the promise of further advance more bright.

As a temporary measure, intended only to improve existing conditions, the result has more than justified the expectations of the Council.

It is, however, only a temporary result and with the graduation of younger men and the expansion of courses in sanitation in the medical schools, the value of such correspondence and short-time courses is passing, if indeed it has not already passed, and the Council now faces the problem of proper qualifications of the health officers of the future. The young graduate from the better medical schools today is not lacking in theoretical knowledge of infection and of immunity, natural and acquired, and of the various ways in which the physician may assist the processes of cure.

He may be prepared, so far as the general bacteriological background goes, to superintend the work of preventing an outbreak of communicable disease in a community or of checking it, should any such disease become epidemic. He lacks, however, the practical applications to public health work required of the health officer, and commonly omitted in medical school courses in favor of general therapeutics and diseases of special organs. He has no knowledge of his rights as health officer under the law, nor of his obligations as a state official. He has no experience or training in water supply, in sewage and wastes disposal, in ventilation, in muscle fatigue or in dietetics. He has no experience or training in dealing with the health of a community rather than with the individual, in so ordering conditions that disease is prevented rather than cured, in educating his clientele rather than in treating them.

Such training, involving as it does an altogether different viewpoint, is hardly to be expected in a medical school. It must come from a school whose course is framed distinctly for such a purpose, and the Council looks forward confidently to the time when such schools as now exist at Harvard and at Johns Hopkins, granting the Degree of D. Ph. to graduate physicians after two years' study, will be a prerequisite to appointment as health officer to every city of the State. It was with rare foresight that the framers of the Public Health Law indicated that confidence by establishing that any physician holding a certificate in public health from a school approved by the Regents in a course approved by the Council should without other qualifications be eligible to appointment as health officer.

But there must be created a demand for trained health officers in order to justify a young man in spending the extra year after the long period of study now required for an M. D. Degree. The people of the State must become cognizant of the greater safety of living in the care of a competent health officer. They must give evidence of their belief by allotting a reasonable competence to such an official, and they must realize their own duty to cooperate in matters of public health so that the knowledge and training of the health officer shall not be exercised in vain.

The Council is ready to adopt more rigid requirements and doubtless there will not be lacking young men willing to qualify, so soon as the communities make the demand; meantime each community continues to purchase such a degree of public health as it desires.

The efforts of the Council are now directed toward the improvement of these emergency courses for health officers, the persuasion of prospective and actual health officers to take them, and the enlistment of the public interest for its own sake in the establishment of higher standards, and the provision of adequate compensation.

Routine and Emergency Activities

The Sanitary Code.— In the routine work of the year many suggestions for the amendment of the Sanitary Code have been considered. Several of them came as usual from the Sanitary Supervisors — others were referred to them for advice; and such cooperation marks the high character of their work and their devotion to the interests of the communities which they so ably serve.

One of the changes in the Code made during the year deals with the manufacture and sale of shaving brushes. It has been brought to the attention of the Council that anthrax, a germ disease, a particularly fatal disease to man, was being transmitted through the medium of shaving brushes made from horsehair. Such brushes came into common use during the war when better materials were not to be obtained in sufficient quantities. At that time the Code was amended requiring that the material used in the manufacture of all shaving brushes be sterilized before sale. Subsequently, it became apparent that complete sterilization of such material was not being done, partly because the spores of the anthrax bacillus are so resistant that they withstand the usual process of sterilization. Hence, although the contaminated material is only known to come from certain foreign countries, it was deemed imperative in this new amendment to forbid the manufacture or sale of shaving or lather brushes made from horsehair, and Regulation 6a of Chapter VII of the Code was amended accordingly.

This emergency amendment to the Sanitary Code is noteworthy for two reasons. First, it is contrary to that tendency of modern health administration, followed whenever practicable by the Council, which constantly strives to achieve its aims with the least possible interference with the convenience of citizens or the interest of business. Notable success in this conservative and salutary course is achieved by closely following the growing knowledge of germs and the lessons of modern epidemiology.

In this case, however, the only way in which the State Department of Health could meet this real peril to a considerable number of its citizens, was by stopping this phase of manufacture and trade forthwith and altogether, so far as the Code can do it. Fortunately, in this instance the Council has received assurance of the acquiescence of the manufacturers in the proposed curtailment of their business.

The second point of interest in this action is, that whatever the Department of Health of the State of New York, or any other single state, or any unofficial combination of states, may do to try to ward off the dangers of anthrax importation — and this danger may go far beyond the bailiwick of shaving brushes — should the infection of cattle or the contamination of the soil become widespread in this country — such efforts are temporizing, local, limited in efficiency, and do not hit the sources of danger. The remedy lies in stopping the importation of merchandise contaminated with anthrax, or securing its adequate disinfection — preferably before shipment — or at any rate before it is distributed in the channels of manufacture and commerce.

Another noteworthy addition to the Code was Regulation 41a of Chapter II requiring the health officer to report to the State Department of Health immediately whenever an outbreak of diarrheal disease comes to his attention. This addition was made necessary by the large number of such outbreaks occurring in various parts of the State. Not having been before designated in the Code as reportable, the Division of Communicable Diseases learned of them only casually, and usually after the outbreak had ceased. If such outbreaks are to be studied and prevented, immediate knowledge of their existence is necessary. It is confidently to be hoped that in the future intensive studies may be made of the causation and prevention of these epidemics of mild but, especially in children, very important intestinal disorders.

A third change in the Sanitary Code deserving of special mention requires the health officer to cause the confinement of an animal suspected of having rabies or to cause such animal to be killed and proper laboratory examination to be made so that the diagnosis of the disease in the animal may be confirmed and preventive treatment, if required, promptly initiated.

All of the above and other amendments to the Sanitary Code enacted during the year are given in full as Appendix I which is attached to this report.

The desirability of changing the regulations of the Code regarding the grading of milk and cream was fully discussed at several meetings of the Council, but it was concluded that no changes be made at present.

Other changes in the Code suggested to the Council dealt with the control of communicable diseases. These suggestions would have defined more clearly and limited more closely the duties of the local health officer. After consideration at several meetings of the Council it was decided that discretionary powers should remain with the local health officer, and that better control of the communicable diseases would be secured by leaving a wide field over which the local health officer might exercise his own initiative.

Qualifications of the Sanitary Supervisors.— The Council amended the regulation for qualifications of Sanitary Supervisors previous to the last examination for this position. This regulation is submitted attached hereto as Appendix II.

Health Officer Exemptions.— The applications of 147 health officers for exemption from the educational qualifications for health officers established by the Council were passed upon during the year.

One of the serious difficulties encountered in the effort to safeguard the health interests, especially of small communities, by the establishment of certain required standards of modern knowledge and of experience in the health officers of the State, has been the dearth of physicians in many rural districts. And in too many instances the Council has been forced to sanction the appointment of local health officers, not in its judgment qualified by education or training to afford to their constituents the protection against disease and the help in emergencies which science today freely offers, because they were the only available candidates under the existing law requiring so many small units of health administration, and it was a question of them or nothing.

The situation is due to the following:

1 Inadequate per capita allowance in rural districts.

2 The lack of physicians in rural districts.

3 The advanced age of many physicians in rural districts and the absence of public health instruction at the period in which their medical education and training were received.

4 The present inadequacy of the instruction in public health in medical schools.

Thus there is no pecuniary incentive to a career in public health for physicians or even for them to take the minimum instruction required for their work, and there is neither on the part of physicians nor of the lay public a general appreciation of this situation in which on the one hand the medical profession cannot or does not become trained or qualified; and on the other hand, the citzen has no practical demonstration of the needs or benefits of fully trained and qualified health officers.

In many such cases, even the tender of the short emergency courses of instruction in modern public health, provided at the request of the Council by a few public-spirited colleges and expert teachers, were declined by candidates, ineligible without them, because the utter pittances which many coummunities offer under the designation of "compensation" is no lure to an aspirant for the responsibilities and hardships and the too-often thankless tasks of the rural health officer.

Health Officer Courses.— During the year the special courses of instruction for health officers have been continued at New York city, Syracuse and Albany. A total of more than 600 health officers have either completed or are now taking one or the other of these courses. As a result of these elementary courses of instruction the work of the local health officers of the State has greatly improved.

Institutes for Public Health Nurses.— The Council gave its approval to a new field of emergency educational work — short intensive courses of instruction for public health nurses, especially for those already in the field. These courses or "Institutes" have been of two weeks' duration and have been given in New York, Syracuse and Albany. It is hoped that funds will be made available so that these Institutes may be made an annual feature. Attached as Appendix III are programs of one course for health officers and one of the institutes for public health nurses.

Poliomyelitis.— During the summer of 1921 a severe outbreak of acute anterior poliomyelitis occurred. This centered chiefly in and about the city of Utica — about one-third of the cases occurring in this district. In the control of this situation the Division of Communicable Diseases was assisted by the active cooperation of one of the members of the Council, Dr. Flexner, who not only advised with the Division but addressed the physicians of the district involved and aided them by his extensive knowledge and wide experience with this disease.

Tuberculosis Hospitals.— The Council caused an investigation to be made of the problem of dealing with disorderly and incorrigible patients in the tuberculosis hospitals of the State. The report of this investigation shows that advantage is not being taken of the existing provisions of the law. A large percentage of these patients have been discharged from the hospitals instead of having been kept there under legal restraint. The advisability of so amending the law that the hospital superintendent may bring about the commitment to a penal institution of a patient who enters the hospital vountarily and who conducts himself in a disorderly manner while in the institution, by providing for one hearing before a magistrate, instead of two hearings — one before the health officer and one before the magistrate — as the law now by implication requires, should be considered.

Sanitary Condition of Palisades Interstate Park.— The report of the inspection of the sanitary conditions of the Palisades Interstate Park by the Division of Sanitary Engineering of the State Department of Health was considered by the Council. A most thorough investigation was made, special consideration being given to water supplies and methods of sewage disposal of the various camps in the park, as well as of the bathing beaches maintained by the park along the Hudson river. In a large number of instances it was found that the water supplies were subject to active pollution and recommendations for their abandonment and for insuring safe water supplies were made. In most instances it was found that the methods of sewage disposal were adequate. In one instance, however, it was reported that sewage was being pumped into the Hudson river in close proximity to one of the bathing beaches; this should be discontinued. The Council urges that the recommendations embodied in this report be called to the attention of the Palisades Park Commission and that they be carried out at a date as early as possible.

Child Health Districts.— Following a careful study of the conditions of child health the Council recommends:

(1) That boards of supervisors of counties be authorized to constitute a county or part of a county as a child health district and to provide for such district a child health board authorized and equipped to take all suitable steps for the protection and welfare of maternity and infancy and for the protection of the health of the children generally. Among the duties and powers of such child health boards when established should be the following:

(a) the establishment of child consultation clinics at which prospective mothers can secure medical examination and advice, and at which babies may be examined and their mothers advised as to their care and treatment;

(b) the employment of visiting public health nurses to visit and advise with expectant mothers;

(c) the employment, where needed, of domestic aids to assist for a few days when no other help is available at the time of child birth in the care of the newborn baby, the care of older children, and in other urgent household duties, under the care of the public health nurse.

(2) That the Division of Child Hygiene of the State Health Department be provided with such additional help as may be needed for assisting in the establishment of effective supervision of the local child health boards.

(3) That provision be made for a more efficient medical inspection of school children, especially in rural districts, and for the correction of defects discovered among them.

(4) That by all practicable methods the discovery and correction of malnutrition among school children, preventive and corrective dental care, and special care for children exposed to tuberculosis be encouraged.

All of which is respectfully submitted.

Dated, *January* 31, 1922.

HERMAN M. BIGGS,
Chairman.
HOMER FOLKS,
Vice-Chairman.

MRS. ELMER BLAIR,
EDWARD H. MARSH,
Secretary.

APPENDIX I

AMENDMENTS TO SANITARY CODE

CHAPTER II

Communicable Diseases

The following amendments to the Sanitary Code were adopted by the Public Health Council during the year 1921:

Regulation 2-b of Chapter II of the Sanitary Code is hereby amended to read as follows:

Regulation 2-b. Rabid or Vicious Animals.— It shall be the duty of every physician or other person to report to the local health officer within whose jurisdiction such person is, the full name, age and address of every person who has been bitten (a) by a rabid animal, (b) by an animal suspected of being rabid, within twenty-four hours from the time when such fact comes to his knowledge.

It shall be the duty of the health officer to transmit promptly these reports to the state department of health.

Every animals that has rabies, or that shows symptoms of rabies, or has been bitten by another animal affected with or showing symptoms of rabies, shall be confined under close observation in some secure place by the person owning or having possession of such animal for such length of time as may be deemed necessary by the local health officer for the purpose of determining whether such disease exists. In the event that no person is found owning or having possession of such animal, confinement shall be made or provided for by the local health officer.

Every health officer shall require the confinement under close observation of any animal of a kind subject to rabies which has attacked or bitten any person, and which in his judgment is vicious or unsafe to be at large, for such time as he regards as necessary, or he may cause such animal to be killed. Whenever any animal which has bitten any person and which has had rabies or any symptoms of rabies dies or is killed it shall be the duty of the health officer to see that the head of the animal is at once removed and sent with all data to the state veterinary college at Cornell for examination, and all the facts shall also be immediately reported to the state department of health.

This regulation as amended took effect January 1, 1922.

Regulation 10 of Chapter II is hereby amended to read as follows:

Regulation 10. Diphtheria; Material for Cultures to be Submitted.— In every case of illness which there is reason to suspect is diphtheria, it shall be the duty of the attending physician or, if the local health authorities so require, of the health officer promptly to take material for cultures from the troat of the suspected person and submit the same for examination to a laboratory approved for this purpose by the state commissioner of health.

This regulation as amended took effect January 1, 1922.

Regulation 10-a of Chapter II is hereby amended to read as follows:

Regulation 10-a. Typhoid or Para-Typhoid Fever; Samples of Blood to be Submitted.— In every case of illness which there is reason to suspect may be typhoid or para-typhoid fever it shall be the duty of the attending physician to take a sample of the blood of the suspected person and submit the same for an agglutination test to a laboratory approved for this purpose by the state commissioner of health.

This regulation as amended took effect January 1, 1922.

Regulation 34 of Chapter II is hereby amended to read as follows:

Regulation 34. Quarantine When a Patient is Not Properly Isolated.— When any case of diphtheria, encephalitis lethargica, epidemic serebrospinal meningitis, measles, scarlet fever, smallpox, poliomyelitis, acute anterior (infantile paralysis), or typhus fever is not or cannot be properly isolated on the premises and cannot be removed to a suitable hospital, it shall be the duty of the local health officer to forbid any member of the household from leaving the premises, except under such conditions as he may specify.

This regulation as amended took effect January 1, 1922.

Regulation 36 of Chapter II is hereby amended to read as follows:

Regulation 36. Minimum Period of Isolation.— For the purposes of this code, the minimum period of isolation is hereby declared to be as follows:

Chickenpox, until twelve days after the appearance of the eruption and until the crusts have fallen and the scars are completely healed.

Diphtheria (membranous croup), until two successive cultures taken from the nose and throat at intervals of not less than twenty-four hours, have been examined and found negative in a laboratory approved for this purpose by the state commissioner of health, the first of such cultures being taken not less than nine days from the day of onset of the disease.

Epidemic cerebrospinal meningitis, until two weeks after the temperature has become normal or until three successive cultures, obtained from the nasopharynx at intervals of not less than five days, shall be found free of meningococci upon examination in a laboratory approved for this purpose by the state commissioner of health.

Measles, until at least five days after the appearance of the rash.

Mumps, until two weeks after the appearance of the disease and one week after the disappearance of the swelling.

Poliomyelitis, acute anterior (infantile paralysis), until three weeks from the day of the onset of the disease.

Scarlet fever, until thirty days after the development of the disease and until all discharges from the nose, ears and throat, or suppurating glands have ceased.

Smallpox, until fourteen days after the development of the disease and until scabs have all separated and the scars completely healed.

Typhoid or para-typhoid fever, if the patient's occupation involves the handling of milk, dairy products, or other food, until all signs of the disease, or all secondary or complicating infections incited by the agents of these diseases have disappeared, and until two successive specimens of the intestinal discharges of the patient have been taken at an interval of not less than seven days and have been examined in a laboratory approved for this purpose by the state commissioner of health and found to be free from typhoid or para-typhoid bacilli.

Whooping cough, until eight weeks after the development of the disease or until one week after the last characteristic cough.

This regulation as amended took effect January 1, 1922.

Chapter II of the Sanitary Code is hereby amended by adding thereto a new regulation to be known as regulation 41-a, and to read as follows:

Regulation 41-a. Notification of Diarrheal Outbreaks.— Whenever there shall occur in any municipality an outbreak or an unusual prevalence of diarrhea, gastroenteritis, enteritis, colitis, enterocolitis, cholera nostra, cholera infantum or other disease in which diarrhea is a prominent symptom it shall be the duty of the health officer to report immediately the existence of such outbreak to the state department of health by telegraph or telephone. Local health officers shall exercise due diligence in discovering the occurrence of such outbreaks or the unusual prevalence of such diseases.

This new regulation took effect November 1, 1921.

CHAPTER VII

Miscellaneous

Regulation 6-a of Chapter VII of the Sanitary Code is hereby amended to read as follows:

Regulation 6 a. Manufacture or Sale of Articles Which May Be Contaminated with Anthrax.— No person shall manufacture, sell or offer for sale a shaving or lather brush containing horsehair.

This regulation shall take effect throughout the state of New York, except in the city of New York, on the first day of January, 1922.

APPENDIX II

Qualifications of Sanitary Supervisors

Sanitary Supervisor, State Department of Health. $3,500. Age limits, 26 to 50 years. The appointee will have administrative health control as direct representative of the State Commissioner of Health in a district comprising several counties. Candidates must be physicians and graduates of recognized schools of medicine. They shall (a) have served as health officer of a city, town or village having a population of not less than 5,000 persons for a period of at least four years; or (b) shall have received instruction approved by the Public Health Council, or a duly authorized committee thereof, in sanitary science, including five hours of instruction per week during the school year in an educational institution, and shall have had at least two years of experience in public health work; or (c) shall have received a degree, certificate or diploma in public health, granted after the completion of a course approved by the Public Health Council, in an educational institution; or (d) shall have submitted proof satisfactory to the Public Health Council, or a duly authorized committee thereof, that they have actually engaged in public health work of such a character as shall qualify them for the duties of the position. Appointees will not be allowed to engage in the regular practice of medicine or in any other regular occupation or business which will interfere with the full discharge of their duties. Subjects of examination: Written examination relating to the duties of the position, relative weight, 4; education, training, experience and personal qualifications, relative weight, 6. An interview may be required.

APPENDIX III

INSTITUTE FOR PUBLIC HEALTH NURSES OF NEW YORK STATE

Given by the State Department of Health in New York City

The New York State Department of Health will conduct a two weeks' institute in New York city, from June 13 to June 25, especially for the benefit of the public health nurses of the State who have not previously had an opportunity to receive instruction in the special lines considered.

The work of the institute will include all phases of public health nursing from both the technical and administrative standpoints. The course will consist of thirty-nine hours devoted to didactic lectures and thirty-six hours to field work, upon the completion of which an examination will be given to test the knowledge of the student in the subjects covered.

The following shows the subjects to be considered and the number of hours to be devoted to each:

SUBJECT	Lecture hours	Field work hours
Child Hygiene	8	9
Industrial Hygiene	2	3
Milk	2	6
Bacteriology	2	6
Vital Statistics	2	..
Communicable Diseases	7	3
Tuberculosis	2	3
Venereal Diseases	2	3
Sanitation	1	3
Public Health Law and Administration	2	..
Mental Hygiene	1	..
Dental Hygiene	1	..
Personal Hygiene	1	..
Public Health Education	1	..
Housing	1	..
Diseases of Adult Life	1	..
Social Aspects of Public Health Nursing	1	..
Food and Nutrition	2	..
Total	39	36

	9–10	10–11	11–12	12–1	1–2	2–3	3–4	4–5

Sat. 25th	Hygiene of School Child Dr. Baker	Hygiene of School Child Dr. Baker	Epidemiology Dr. Godfrey	Sanitation Mr. Holmquist		EXAMINATIONS		

The following have consented to participate in the institute in the capacity of instructors:

Dr. S. Josephine Baker, Director, Bureau of Child Hygiene, New York City Department of Health.
Dr. Paul B. Brooks, Assistant Director, Division of Laboratories and Research, New York State Department of Health.
Mr. Bailey B. Burritt, Director, Association for Improving the Condition of the Poor.
Dr. E. M. Giddings, Resident Physician, Willard Parker Hospital.
Dr. Edward S. Godfrey, Jr., Director, Division of Communicable Diseases, New York State Department of Health.
Dr. William H. Guilfoy, Registrar of Vital Statistics, New York City Department of Health.
Dr. L. I. Harris, Director, Bureau of Preventable Diseases, New York City Department of Health.
Mr. C. A. Holmquist, Sanitary Engineer, New York State Department of Health.
Dr. George C. Kirby, Director, Psychiatric Institute.
Dr. Charles Krumwiede, Assistant Director, Research Laboratory, New York City Department of Health.
Dr. Joseph S. Lawrence, Director, Division of Venereal Diseases, New York State Department of Health.
Dr. W. H. Leak, Supervisor, Oral Hygiene, New York County Chapter American Red Cross.
Dr. Malcolm F. Lent, Director, Division of Tuberculosis, New York State Department of Health.
Dr. W. T. Longcope, Attending Physician, Presbyterian Hospital, New York City.
Dr. Edward H. Marsh, Consultant in Venereal Diseases, New York State Department of Health.
Dr. Willis C. Noble, Assistant Director, Division of Laboratories and Research, New York State Department of Health.
Dr. Frank Overton, Sanitary Supervisor, New York State Department of Health.
Mr. B. R. Rickards, Assistant to the Deputy Commissioner, New York State Department of Health.
Dr. M. A. Schroeder, Bacteriologist, Research Laboratory, New York City Department of Health.
Dr. F. W. Sears, Sanitary Supervisor, New York State Department of Health.
Dr. R. J. Wilson, Director, Bureau of Hospitals, New York City Department of Health.
Miss Emma A. Winslow, Lecturer, Department of Economic and Social Science, Teachers' College.

The institute will be limited to thirty nurses, as it is thought that such limitation will bring about closer contact between instructors and students and the value of the instruction will thus be enhanced.

No charge will be made for tuition. The expenses therefore will be limited to the cost of lodging, subsistence and travel, and need not exceed twenty dollars per week.

Most of the didactic teaching will be given at the New York University, and Bellevue Hospital Medical College, 26th street and First avenue, New York city. Announcement will be made during the institute of the places where the field work instruction will be given.

For further particulars, address Dr. E. H. Marsh, State Department of Health, 25 West 45th street, New York city.

APPENDIX III

Course for Health Officers and Physicians, New York University

With the cooperation of the Health Department of New York city, New York University provides two courses in preventive medicine which meet the requirements established by the Public Health Council of New York State. Although intended primarily for health officers, anyone who is interested in public health problems and who possesses the educational qualifications may take these courses.

The first or *residence* course begins September 15, 1920, and requires attendance every Wednesday for a period of twenty-four weeks, the work being divided into fall and spring semesters with an interval of three months during the winter to accommodate health officers in rural districts, for whom traveling is difficult at this time.

This course covers the work of the health officer in all the usual phases of preventive medicine, both technical and administrative. The program as outlined below shows its scope.

The following textbooks are recommended for reference and study in connection with the lectures and field work. The university is able to supply these enrolled students at 25 per cent discount on the publishers' price.

System of Hygiene and Preventive Medicine, W. H. Park, *or* Preventive Medicine and Hygiene, M. J. Rosenau	$7 50
Pathogenic Micro-Organisms, Park & Williams	6 00
Sources and Modes of Infection, C. V. Chapin	3 50
Manual for Health Officers, J. S. MacNutt	3 50
Sanitation, Water Supply and Sewage Disposal, W. P. Gerhard	2 00
Health Work in Schools, Hoag & Terman	1 85

In addition to the foregoing, several miscellaneous pamphlets are furnished to the students at cost.

The fees for the course include a five-dollar matriculation fee for those who have not been previously matriculated with New York University, and a twenty-five-dollar tuition fee. Students of previous years in any of the public health courses are invited to attend as many sessions as possible without additional charge.

Program

FIRST DAY

9:30 A. M. Introduction to course
Dr. William H. Park, Professor of Bacteriology and Hygiene, New York University

10-12 M. Lecture and demonstration of general bacteriology and technique
Dr. Willis C. Noble, Assistant Professor of Hygiene, New York University

1- 3 P. M. Practical laboratory work: Preparing, staining and examining specimens
Dr. Noble

SECOND DAY

9:30 A. M. Quiz on previous week's work
10-12 M. Diphtheria and the exanthemata; diagnosis and treatment
Dr. Giddings, resident physician, Willard Parker Hospital
1- 3 P. M. Diphtheria· laboratory diagnosis; the Schick test· antitoxin
Dr. Park; Dr. E. J. Banzhof, Assistant Director, Department of Health, New York City

THIRD DAY

9:30 A. M. Quiz on previous week's work
10-12 M The enteric diseases, symptomatology, epidemiology, control of, etc.
Dr. Charles Krumwiede, Jr., Assistant Professor of Bacteriology and Hygiene, New York University
1- 3 P. M. Laboratory diagnosis of the enteric diseases, blood cultures, agglutination reactions, etc.
Dr. Noble

FOURTH DAY

10:00 A. M. Visit to public health exhibit, American Museum of Natural History
Lecture on water purification and sewage disposal
Mr. A. J. Provost of the Pease Laboratories
7:00 P. M. Inspection of a water filter
Mr. Provost

FIFTH DAY

9:30 A. M. Quiz on previous week's work
10:00 A. M. Lecture on milk, and milkproducts; production, pasteurization, etc.
Dr. M. A. Schroeder, Bacteriologist, Department of Health, New York City
1- 3 P. M. Milk. Laboratory examination
Dr. Schroeder

SIXTH DAY

10:00 A. M. Inspection of pasteurization plant
Dr. Herbert D. Pease, Director of Pease Laboratories, New York City
* *P. M.* Inspection of sewage disposal plant
Mr. Provost

SEVENTH DAY

* Dairy inspection and scoring
Dr. Schroeder

EIGHTH DAY

9:30 A. M. Inspection of slaughter houses
Dr. Aaron Silkman, Chief Veterinarian, Department of Health, City of New York
1- 3 P. M. Lecture—Cold storage
Dr. Pease
* Inspection of cold storage plant

NINTH DAY

10:00 A. M. Child hygiene, prenatal care, infant care, care of pre-school child, school child
Dr. S. Josephine Baker, Director, Bureau of Child Hygiene, Department of Health, City of New York
1- 3 P. M. Child hygiene continued

---

* Hour to be announced

TENTH DAY

10:00 A. M. Child hygiene—inspection of baby welfare station. School medica inspection

Dr. Baker

1- 3 P. M. The management of communicable diseases in the schools

Dr. John A. Smith, Secretary, New York State Department of Health

ELEVENTH DAY

9:30 A. M. Quiz on previous week's work

10-12 M. Cerebrospinal meningitis; differential diagnosis, spinal puncture; administration of antimeningococcus serum

Dr. Josephine B. Neal, Bacteriologist, Department of Health, City of New York

1- 3 P.M. Pneumonia, clinical types; bacteriology of; type differentiation of pneumococcus; administration of antipneumococcus serum

Dr. Krumwiede

TWELFTH DAY

9:30 A. M. Quiz on previous week's work

10-12:30 M. Syphilis—laboratory methods of diagnosis; demonstration of *Treponema pallidum.* The complement fixation test

Dr. Noble

1:30-3:30 P. M. Syphilis—clinical lecture; demonstration of administration of arsphenamine

Dr. William B. Trimble, Professor of Dermatology and Syphilology, New York University

THIRTEENTH DAY

9:30 A. M. Quiz on previous week's work

10-12 M. Tuberculosis: Laboratory diagnosis of

Dr. Noble

1- 3 P.M. Tuberculosis: Early diagnosis of; treatment and control of

Dr. E. S. McSweeny, former Director of Sea View Sanatorium; former Supervisor of Tuberculosis, New York State Department of Health

FOURTEENTH DAY

9:30 A. M. Quiz on previous week's work

10-12 M. Manufacture and use of smallpox virus and rabies virus

Dr. Bertha Von H. Anthony, Bacteriologist, Department of Health, City of New York

1- 3 P. M. Smallpox: Differential diagnosis, epidemiology, etc.

Dr. William L. Somerset, Chief Diagnostician, Department of Health, City of New York

FIFTEENTH DAY

10:00 A. M. Oral examination

Drs. Park, Noble, Marsh and Mr. Provost

1:00 P. M. Written examination

SIXTEENTH DAY

10:00 A. M. Diseases of adult life

Dr. Hermann M. Biggs, Commissioner of Health, State of New York

1- 2 P. M. Duties of health officer with the insane

Mr. Everett L. Elwood, Secretary, State Hospital Commission

2- 3 P. M. Mental hygiene

Dr. George H. Kirby, Physician, Manhattan State Hospital for Insane

Seventeenth Day

9:30 A. M. Quiz on previous week's work

10-12 M. Rural hygiene

Dr. Frank Overton, Sanitary Supervisor, New York State Department of Health

1- 3 P. M. Industrial hygiene

Dr. Louis I. Harris, Director, Bureau of Communicable Diseases, Department of Health, City of New York

Eighteenth Day

10-12 M. Routine duties of a health officer

Dr. Perley H. Mason, Sanitary Supervisor, New York State Department of Health

1- 3 P. M. Hospital management of communicable diseases; disinfection

Dr. Robert J. Wilson, Assistant Professor of Bacteriology, New York University

Nineteenth Day

9:30-12 M. Parasitology of the blood and the intestinal tract

Dr. Arthur Mandel, Professor of Clinical Pathology, New York University

1- 3 P. M. Immunity—lecture

Dr. Krumwiede

Twentieth Day

9:30-12 M. Parasitology of blood and the intestinal tract

Dr. Mandel

1- 3 P. M Epidemiology—lecture

Dr. George A. Soper, former Major, Sanitary Corps, United States Army

Twenty-first Day

9:30 A. M. Quiz on previous week's work

10-12 M. Suppression of nuisances—lecture and discussion

Dr. Overton

1:30-3 P. M. Address

Dr. Royal S. Copeland, Commissioner of Health, City of New York

Twenty-second Day

9:30 A. M. Quiz on previous week's work

10-12 M. Vital statistics—lecture and discussion

Dr. William H. Guilfoy, Registrar, Department of Health, City of New York

1- 3 P. M. Public health nursing

Dr. John A. Smith

Twenty-third Day

9:30 A. M. Quiz on previous week's work

10-12 M. The health officer and the public health law

Mr Joseph A. Warren, Counsel, New York State Department of Health

1- 3 P. M. Health administration in small communities

Dr. Charles C. Duryee, Sanitary Supervisor, New York State Department of Health

Twenty-fourth Day

Final examinations

The second or *reading* course, which consists largely of reading, requires but one week of residence in New York city, and is given for the benefit of health officers who reside at such a distance from the city that attendance at the residence course is impossible. This course may be begun at any time and *must* be completed within one year of the time of enrollment unless some special reason exists which makes this impossible.

For convenience, the work is divided into ten subjects, each of which is to be completed and to be followed by an examination before the next subject is commenced. The purpose of the examination, which is taken at home, is to test the health officer's general understanding of the completed subject. The subjects may be taken in any order desired, but it is recommended that the order given below be followed —

1. Communicable diseases
2. Tuberculosis
3. Bacteriology and disinfection
4. Routine work of a health officer
5. Child hygiene
6. Milk and other foods
7. Water supply and waste disposal
8. Hygiene of home and workshop
9. Mental diseases from the public health standpoint
10. Vital statistics

It is permissible for the student to consult textbooks before answering the questions. The papers are reviewed and rated by competent examiners. A series of questions which act as a guide to the study of each subject have been prepared and are forwarded as required.

The textbooks which are recommended and upon which the examination questions are based are the same as those previously mentioned in connection with the residence course.

The week's work in the city can be taken at the end of the course, or at an earlier period if the prescribed reading on communicable diseases, water, milk and bacteriology has been completed. The residence week is held three or four times during each year, but only when ten or more students desire to attend. The work is divided as follows:

MONDAY

9:00 A. M. Registration

9:00 A.M.-1:00 P. M. Bacteriological Laboratory, University and Bellevue Hospital Medical College, 26th street and First avenue. Study of bacteriological and serological methods of diagnosis, diagnostic examinations for diphtheria, typhoid fever, malaria, tuberculosis, gonorrhea and syphilis. Bacteriological examinations of milk and water

Drs. Park, Krumwiede, Noble and Zingher

2:00 P. M.-6:00 P. M. Willard Parker Hospital and Research Laboratory of the Department of Health, 16th street and East river. The diagnosis and treatment of measles, scarlet fever, diphtheria, whooping cough and any other communicable diseases located at the time in the hospital; the methods of producing antitoxins, Pasteur treatment, vaccine virus and other protective substances; disinfection

Drs. Williams, Banzhof, Neal, Anthony, Schroeder, Giddings, Thompson and Hatfield

TUESDAY

Same schedule as Monday

WEDNESDAY

* Inspection of the process of pasteurizing milk, the hygienic exhibit at the American Museum of Natural History and conference on the care of milk, the purification of water and the disposal of sewage

Drs. Pease, Schroeder and Mr. Provost

THURSDAY

* Inspection of a water and sewage purification plant, of an infant milk station and of a health center

Drs. Pease, Schroeder, Mr. Provost and inspectors of the Department of Health

FRIDAY

9:00 A. M.-1:00 P. M. Food, meat and factory inspection

Dr. Silkman

2:00 P. M.-4:00 P. M. Demonstration of the technique of treating syphilis. A consideration of the handling of tuberculosis from the standpoint of the health officer

Drs. Harris, Hubbard, McSweeny and Marsh

SATURDAY

9:00 A. M.-11:00 A. M. Written examinations
11:00 A. M.-1:00 P. M. Optional inspections

The fee for the above course is $25 in addition to the matriculation fee of $5 for those who have not previously attended the university. The necessary books may be borrowed from the university upon the payment of a fee of $15, ten of which will be returned to the student if the books are returned *in good condition within one year of the time of obtaining them.*

CERTIFICATE

Students who successfully complete either of the above courses will be granted an appropriate certificate.

REGISTRATION

Those desirous of registering for either of these courses should address Dr. Edward H. Marsh, Assistant Director, Room 804, 25 West 45th street, New York city; or, Dr. William H. Park, Director, 338 East 26th street, New York city.

---

* Hours to be announced at Monday session

DIVISION OF PUBLIC HEALTH NURSING

DIVISION OF PUBLIC HEALTH NURSING

HERMANN M. BIGGS, M.D., *Commissioner of Health, Albany, N. Y.:*

SIR.— I have the honor to submit to you the attached report of the Division of Public Health Nursing for the calendar year 1921.

Respectfully submitted
MATHILDE S. KUHLMAN R. N.
Director

January 26, 1922

The work of the Division of Public Health Nursing has been marked during the year 1921, by additional demands in the administrative duties, and by increasing activities in field work through the staff of supervising nurses.

Because of the nature of the work this Division has been largely engaged in assisting other divisions of the department in carrying out their programs, and has given supervision through the supervising nurses and correspondence, to the local nurses engaged in public health nursing throughout the State.

A roster of all public health nurses in New York State (outside of New York city) numbering over 1,000 is kept up to date by this Division, and supervising nurses visit local nurses once in six months or more often where necessary. Lectures on public health nursing subjects have been given to student nurses, hospital alumnae associations and groups of public health nurses by the Director. Institutes for Public Health Nurses were conducted in New York, Syracuse and Albany and plans formulated for an Institute to be held in Buffalo early in 1922. The Institutes consist of a two weeks' series of lectures on all phases of Public Health Nursing by members of the staff of the State Department of Health and selected specialists, with demonstrations and observations of field work and visits to institutions and industries. Thirty to fifty nurses have enrolled for each Institute. They expressed much appreciation of this educational opportunity.

Supervising nurses of this division assisted in organizing and conducting group consultation clinics in three counties. This consisted of field work preliminary to the clinic and nursing service in clinics for chest examination, pediatrics, orthopedics, gynecology, diseases of adult life, laboratory examinations, x-rays and other branches, usually conducted in a school building as one clinic with a rural county as the field of activity.

Seven supervising nurses have given aftercare to 1,498 patients crippled from infantile paralysis. The aftercare consists of visits under the supervision of the family physician and the state orthopedic surgeon, giving muscle exercises and teaching members of the family the care of such patients, the proper adjustment of braces and apparatus.

Clinics were organized and nursing service given in 62 localities and patients visited and instructed in 532 communities. Details of this work are given in the report of the Division of Child Hygiene.

Two supervising nurses are assigned to the Division of Tuberculosis, to instruct and supervise county and city nurses doing tuberculosis work; to visit dispensaries and assistant nurses in the conduct of their work and in record keeping and submitting properly made out reports.

Tuberculosis surveys were conducted in three whole counties and parts of 2 others. Thirty-one hospitals and dispensaries were visited in the interest of tuberculosis nursing, 30 county nurses were visited and instructed, 68 conferences were held with health officers, physicians, nurses, members of boards of supervisors and local tuberculosis committees, and other organizations and individuals interested in the work. One hundred and six patients were visited and instructed in home care and in regard to clinics and sanatoria.

In the work of child hygiene the supervising nurses assisted in conducting children's health conferences in 198 localities in the State. In 30 extremely rural localities where no local nurses are employed, follow-up work of these conferences was done. Visits were made to physicians and to parents in the interest of securing such corrective treatment as recommended by the physician. Much educational work for child care was accomplished in this way. One hundred and ninety-nine interviews were held with health officers, physicians, members of committees and women's clubs in the interest of children of pre-school age. Nineteen nurses were given special assistance and instruction. Six addresses were made and 27 child welfare stations, day nurseries and boarding homes were visited and inspected by supervising nurses and assistance rendered in establishing stations.

Communicable disease work consisted of investigations and visits of instruction in 73 localities in the care, prevention and control of typhoid fever, smallpox, diphtheria, scarlet fever, measles, whooping cough and dysentery; securing specimens for laboratory examinations where necessary under direction of sanitary supervisor or local health officer. Nurses assisted with vaccinations and Schick tests. Sixty-eight field public health nurses were instructed and assisted in public health nursing of communicable disease.

Meetings of groups of school teachers were attended by one supervising nurse and addresses given in control of communicable disease in schools.

For the purpose of epidemiological study by the Division of Communicable Diseases, one nurse was assigned to a survey of goitre cases in four counties and 35 communities in which a total of 669 cases were found.

The supervising nurse in charge of midwives and day nurseries inspected and supervised 432 licensed midwives in the State outside of New York city. Special visits were made and instruction given to 43 midwives and 47 nurses. Sixteen birth registrations were investigated where incomplete information was given. Eleven day nurseries were visited and inspected. Thirty-two conferences were held with health officers and physicians.

Much time was given to general clerical work and correspondence in connection with the work of midwives and in securing affidavits and preparing evidence on 12 cases where licenses were refused.

In the venereal disease work, supervising nurses attended 156 clinics which were held in 38 places. Nurses in the field were instructed and assisted in carrying on this work; social service follow-up work was done in connection with four clinics. Conferences and interviews were held with health officers, physicians, nurses and members of boards of health. A survey was conducted in 36 hospitals in the interest of securing information regarding blood examinations. Details of work are given in the report of the Division of Venereal Diseases.

Four supervising nurses were on duty on five of the Indian Reservations of the State until July 1 when lack of appropriation for salaries of two supervising nurses made it impossible to continue the work on more than two of the reservations, the Onondaga and St. Regis.

Children's conferences and tuberculosis clinics were held on the reservations. The nurses give instruction and demonstration in caring for sick and well babies, in supervision, education and care of tuberculous patients and contacts. Much has been accomplished by this work on the reservations in an educational way; less time is spent in giving actual bedside care and more has been done in class instruction and demonstration.

These nurses assist in the prevention of blindness, in securing birth registrations, they give supervision to midwives on the reservation and are vigilant in detecting the first evidence of any communicable disease which may affect the surrounding communities as well as the residents of the reservations.

One supervising nurse in the Division of Public Health Education works in cooperation with farm bureaus for the purpose of instructing rural communities in the elementary principles of home nursing, hygiene and preventive measures. Addresses were given in 160 communities with a total attendance of 7,067 persons. Two hundred and thirty-two demonstrations were made in the care of the sick and in class instruction.

One supervising nurse assists the Director of Public Health Education in securing information and educational matter for the Public Health Nurses' Bulletin and other department publications.

The state supervising nurses are largely engaged in assisting municipalities in the prevention and control of communicable disease, especially where no public health nurse is employed in which case she demonstrates such service; she aids communities in securing proper nursing service where such is considered necessary and is desired by the residents; she educates and demonstrates in the care of the health of the child of preschool age; and supervises and standardizes the work of local nurses, assisting them in carrying on their work in the most efficient way.

DIVISION OF PUBLIC HEALTH EDUCATION

DIVISION OF PUBLIC HEALTH EDUCATION

HERMANN M. BIGGS, M.D., *Commissioner of Health, Albany, N. Y.:*

SIR.— I have the honor to submit the report of the Division of Public Health Education for the year 1921.

Respectfully submitted

B. R. RICKARDS

Director

January 16, 1922

Health News.— The 1921 issues of the HEALTH NEWS were devoted to a discussion of the following public health subjects: two numbers to the diseases of adult life, and one each to poliomyelitis, methods of making sanitary surveys, the control of venereal diseases, relation of the health work of the Red Cross to official state and local health work. The February number was composed of a retrospect of the work of the Department for the year 1920. The remaining issues contained important articles on the Schick test, communicable disease control, the standardization of anti-syphilitic therapy, spinal puncture in diagnosis and treatment, special educational needs of children, modern therapy in asthma and hay fever, group medicine, epidemic encephalitis and heliotherapy in tuberculosis. Each issue has contained an editorial on some timely and important phase of public health.

A questionnaire sent to the readers of the HEALTH NEWS showed approximately 70 per cent of those replying to be in favor of symposiums. Over 80 per cent were of the opinion that the HEALTH NEWS was successfully accomplishing its aims.

Public Health Nurses' Bulletin.—A monthly issue averaging eight pages, serves as an instrument to provide public health nurses, health officers, social workers, executive secretaries and related workers with the trend of movements which modify or define the duties and opportunities of public health nurses in New York State.

The following are some of the subjects presented during 1921: Group consultations for rural districts, rehabilitation of industrial cripples, prevention of epidemics, recent tendencies in the control of venereal diseases, the newer knowledge of nutrition, the use of volunteer service in public health work, prevention of dental caries, the public health nurse and vital statistics, institutes for public health nurses, the relation of nurses employed by private agencies to local health officers, and the relation of the state supervising nurse to the local public health nurse.

Health Officers' Bulletin.— This bulletin has continued to serve as a means of conveying to health officers in convenient form for ready reference changes and additions to the Sanitary Code and the Public Health Law, notices and programs of courses for health officers, instances of effective methods by which outbreaks of communicable disease have been prevented, special information regarding epidemics, legal opinions pertaining to the interpretation of health laws and regulations, and other official and semi-official information regarding which health officers should be promptly advised.

News Letters.— It is frequently important that prompt statewide publicity be given to facts concerning new health laws or regulations, the unusual prevalence of a communicable disease, methods of prevention of seasonal diseases or warning in regard to health menaces. During 1921 thirteen such news letters were sent to the daily and weekly newspapers of the State.

Addresses.— In the absence of a paid staff of lecturers, members of the regular staff and the sanitary supervisors have been called upon through this Division to respond to the numerous requests for addresses on special health topics. In addition several series of health lectures have been arranged and speakers furnished. This work can not be further developed and extended until lecturers are added to the Division, since the assignment of members of the regular staff to this work, takes them away from their regular duties.

Magazine Health Literature.— From time to time health hints and notes have been furnished to editors of Employees' Magazines of the State. These notes have been widely used. The possibilities in the way of spreading health information to the masses by this means is very great in view of the fact that the number of people who can be thus reached is in the neighborhood of 500,000. It is planned to make wider use of this method. Health notes have also been supplied to a number of health and medical journals.

Rural Health Campaign.— During the past year the Healthmobile campaign has been conducted along the same lines as heretofore, work being carried on in 21 counties of the State. The stress has been laid on child welfare and the Healthmobile has been used as an adjunct to child welfare clinics, motion pictures being shown in connection with the meetings and the car being used for the transportation of necessary equipment. It is gratifying that during the two years and more that this work has been in progress the car has kept every engagement, no cancellation of meetings scheduled having been necessary. This campaign continues to be very popular and calls are constantly being received from all parts of the State, the demand being far greater than can be met with the present facilities. On the whole, it is believed that this is one of the most worthwhile educational undertakings of the Department.

Finding from experience in this campaign that the rural districts of the State are most receptive and responsive to educational campaigns on health matters, the Department last year undertook, in cooperation with the Atlantic Division of the American Red

Cross and the State College of Agriculture at Ithaca, the production of a motion picture film showing in detail how the farmhouse may be equipped with a modern plumbing system without the assistance of trained plumbers. This film shows in two reels the whole process of installing modern plumbing in the rural home. It begins with the installing of simple pump and sink in the kitchen, then shows methods of connecting a tank and then having running water, and how later a water heating system can be added. Finally, the plumbing is completed by putting in a bathroom and proper sewage disposal plant. That there is a call for instruction along this line is proved by the many calls which are being received from all over the State for the use of this film. It is planned to put on a systematic campaign in connection with the farm bureaus in about twelve counties. Very cordial cooperation is assured and it is believed that this will be a most practical method of reaching the agricultural communities and of interesting them in better sanitation.

The usual routine work along exhibit lines has been continued. In accordance with policies of recent years, new motion pictures films have been purchased and are in constant demand and use. Eighteen films were shown 218 times during 1921, to a total of approximately 144,000 people. Our collection of lantern slides has been added to materially and has proved very serviceable. In a large proportion of cases the films and lantern slides have been shown in cooperation with meetings held by local agencies and it is felt that this service gives very practical support for many local health movements. Five regular lantern slides lectures were given thirty times to an estimated total attendance of 1,600.

There is a growing tendency to lay increasing stress on these activities rather than on the more formal exhibits in vogue in past years. Experience shows that the use of material of this character is more efficient, economical and generally desirable than the cumbrous exhibits of panels and models which so rapidly become obsolete.

The routing of a speaker, detailed by the Division of Public Health Nursing, to address audiences of rural women usually under the auspices of the Home Bureaus has also been under this Division and while not spectacular it is felt that this work has proved most valuable and is accomplishing a very useful purpose at small expense. In this manner 7,000 people have been instructed in home nursing, hygiene and the prevention of disease. The necessity for public health nurses in rural communities has been stressed in each instance and has been instrumental in the placement of such nurses.

General Public Health Literature.— This Division is responsible for the editing of all bulletins and reports issued by the Department and for the distribution thereof. During the year 453,122 pieces of printed matter were issued by this Division, of which 325,980 were monthly bulletins; 27,000 health circulars and pamphlets sent or given to persons requesting them; 63,530 baby books sent to young mothers and 22,560 pamphlets on suggestions to prospective mothers.

A bibliography for health officers similar to the bibliography for public health nurses issued last year, was prepared and given out to health officers attending the annual conference. With the cooperation of the State Medical Library and the Cornell University Library a complete set of all books listed was exhibited in the registration room of the Conference.

Annual Conference.— The annual conference of health officers and public health nurses was held September 13 to 15 at Cornell University, Ithaca, the preparation of the program and the arrangements being in charge of this Division. Thirty-five papers were read followed by interesting and instructive discussions. Among other important guests were Dr. Simon Flexner of the Rockefeller Foundation, Dr. Allan McLaughlin, Surgeon-General of the United States Public Health Service, Dr. W. F. Snow, Executive Secretary of the American Social Hygiene Association.

Clean-up Campaign.— Suggestions for organized community clean-up work were sent to every health officer during the early spring. A newspaper article outlining the necessity for the work and urging community action was sent to every newspaper in the State. The suggested methods and work apparently were carried out very generally throughout the State.

Aiding Communities in Securing Medical Service.— This work commenced in 1918, has been continued during the past year. Twelve communities have been supplied with physicians, (six through this Department) eight new communities have been added to the list while seven communities previously supplied have again requested assistance showing that physicians sent to them have stayed but temporarily. Ninety-eight physicians wrote for information regarding localities lacking medical service. This Division is doing all it can to alleviate this situation but with the average age of physicians in rural communities constantly increasing and young physicians refusing to take up rural practice conditions are steadily growing worse. Legislative action will ultimately become absolutely necessary if rural communities are to receive adequate medical service.

DIVISION OF TUBERCULOSIS

DIVISION OF TUBERCULOSIS

HERMANN M. BIGGS, M.D., *Commissioner of Health, Albany, N. Y.:*

SIR.— I have the honor to submit the annual report of the Division of Tuberculosis for the year 1921.

Respectfully submitted

FREDERICK W. McSORLEY

Director

February 14, 1922

In 1921 the Tuberculosis Division has continued the activities of the previous year and an attempt has been made, as far as possible, to increase the scope of the work.

With a small staff, 54 clinics have been held in 19 counties. The average attendance was about 30, giving a total of 1,604 patients examined, with the following results: 300 were found positive; 516 were suspicious, 572 needed observation; and 216 were negative. In the "observation" group have been placed those patients — especially children — who, while showing no particularly suggestive signs, were either contacts or below par physically.

Practically all the clinics have been held in the rural districts where hospitals with tuberculosis dispensaries, x-ray and other diagnostic aids were not available. There has been little publicity — the policy being to conduct the clinics on a consultation basis in conjunction with the local physicians. The physicians are invited to send selected cases and the nurses search out contacts. Each patient presents a card signed by his family physician, to whom a detailed report, giving the physical and x-ray findings, diagnosis, and recommendations, is mailed. As a result, practically all applicants for examination have symptoms suggesting pulmonary disease, those requiring care are placed under medical control, and better cooperation with the family physicians is secured. Many more of the local physicians are attending and assisting in the examination of their patients. The clinics, therefore, have an educational as well as a practical value since the physicians have an opportunity to correlate the physical and x-ray findings.

The portable x-ray outfit has been a great aid in diagnosis and has increased the interest in the clinics. Since January 1, 1921, 1,387 radiographs have been taken. The films are brought back to the main office, developed and interpreted and the findings added to the original clinic cards, which are filed for reference.

In New York State, exclusive of New York city, there are 37 county or city tuberculosis hospitals with a total bed capacity of 3,242. Representatives of this Division visit and inspect these institutions, confer with the superintendents and boards of managers and assist them to settle their problems. The superintendents of these hospitals conduct clinics and direct the tuberculosis activities in their counties.

The services of the field agent of the State Department of Health have been valuable in inspecting proposed sites, suggesting plans for new institutions and giving opinions regarding necessary changes or additions in those already in operation.

Two nurses are assigned to this Division; one assists at the clinics and one visits the county nurses. At present there are, engaged in tuberculosis work, 45 county nurses in addition to many others employed by public and private agencies. These nurses cooperate with the local physicians, assisting in the care of patients who are being treated at home. They instruct the patients and their families regarding prophylaxis, aid patients returning from sanatoriums to find proper employment, and do the advance work for clinics. Without their services the tuberculosis campaign could not be carried on successfully.

Reports of all new cases and deaths from tuberculosis are received by this Division, the information is checked and investigated when necessary, and the corrected reports are filed.

The special course of instruction for county hospital superintendents was conducted at Ray Brook in July. Other activities were: Cooperation with the Civil Service Commission in conducting examinations; aiding boards of managers in the selection of hospital superintendents; inspection of tuberculosis dispensaries; lectures and practical instruction in connection with the courses for health officers and nurses (given at Albany in April and December, and the course for nurses in New York in June) and lectures to pupil nurses and lay audiences in various towns and cities.

The following table shows the results of examinations made at the clinics held by this Division in 1921, classified according to different age groups:

AGE	POSITIVE		SUSPICIOUS		OBSERVATION		NEGATIVE		TOTAL		Grand total
	Males	Females	Males	Females	Males	Females	Males	Females	Males	Females

DIVISION OF VENEREAL DISEASES

DIVISION OF VENEREAL DISEASES

HERMANN M. BIGGS, M. D., *Commissioner of Health, Albany, N. Y.:*

SIR.— I have the honor to submit the following report of the activities of the Division of Venereal Diseases for the year 1921.

Respectfully

JOS. S. LAWRENCE

January 31, 1922 *Director, A. A. Surgeon*

During the year of 1921 the Division of Venereal Diseases joined in the general spirit of economy by reorganizing its staff and consolidating work where feasible. The educational, clinical and medical follow-up forces were each reduced as much as was practicable without seriously impairing their efficiency. As the work of the division is more definitely outlined now, it is possible to effect a fairly permanent organization.

Certain demonstrational work which was being conducted at the opening of the year was temporarily discontinued, for example, the assistance tendered the orphanages and state hospitals in making physical and serological examinations of their dependent population and initiating treatment with those found infected. When it was decided to discontinue the manufacture and distribution of arsphenamine the treatment of these dependents could no longer be undertaken by our agents and the work, valuable as it was conceded to be, was interrupted but with the hope that provision would soon be made for its completion.

Education

Considerable attention was given again this year to extending the several features of the educational program. A greater proportion of time was devoted to work in the rural districts than to that in cities, partly because of the solicitation of the very active Home Bureau organization and partly because of our desire to reach all people of the State. With the Home Bureau agents we extended our educational tours to 26 counties where a total of 315 lectures were delivered to an aggregate of more than 25,000 people who also received some of our pamphlets which were passed out at each meeting.

Distribution of Work According to Counties, done in Cooperation with the Home Bureau Organizations

County	No. of Meetings	Attendance
Allegany	7	244
Broome	10	658
Cayuga	7	153
Chenango	9	1,080
Cortland	3	136
Delaware	20	2,606
Erie	12	737
Essex	1	35
Herkimer	17	1,747
Jefferson	19	2,289
Lewis	3	410
Madison	6	570
Monroe	5	283
Nassau	4	125
Niagara	11	400
Oneida	24	1,047
Onondaga	5	270
Orleans	5	550
Otsego	10	530
Steuben	32	3,045
Suffolk	18	1,359
Sullivan	19	3,091
Tioga	16	942
Tompkins	8	220
Ulster	30	2,429
Westchester	14	574
Total	315	25,530

In the following counties the work was aided materially by the use of the field car: Broome, Delaware, Steuben, Sullivan, Tioga.

With the use of the American Social Hygiene Association field car, which is an automobile equipped with a moving picture machine, illustrating the lectures with films was made practicable in rural sections. The field car with its equipment made it practicable also to lecture to audiences at the county agricultural fairs. Almost 100,000 people were reached at these fairs.

County Fairs

With Field Car

PLACE	Date	Lecturer	Attendance exhibit	Number lectures	Attendance lectures
Whitney Point	8/15	Read	5,000	16	4,000
Waterloo	8/23	Read	....	19	2,800
Rome	8/29	Read	10,000	24	8,000
Rochester	9/ 5	Read	16,400	12	6,000
Bath	9/26	Read	25,000	28	20,000
Elmira	10/ 4	Read	12,000	12	1,600
Total with car — 6 fairs			69,000	111	42,400

Without Field Car

PLACE	Date	Lecturer	Attendance exhibit
De Ruyter	8/ 8	Read	1,500
Altamont	9/19	Guerard	20,000
Richfield Springs	9/26	Guerard	6,000
Dundee	10/10	Guerard	300
Total without car — 4 fairs			27,800

Summary

Fairs visited with field car	6
Fairs visited without car	4
Total number lectures given	111
Total attendance at lectures	42,400
Total attendance at exhibits	96,800

In the cities the educational work was done in cooperation with the health officer or with some voluntary organization. We effectively cooperated with a number of health officers in conducting health week programs. The Y. M. C. A. sought our assistance in training their group leaders in the presentation of the subject of social hygiene to classes of boys, as well as in helping them put over educational campaigns in several of the large cities.

The educational activities of the field staff may be briefly summarized:

Total number of lectures	734
Total attendance	122,520
Total number of men in audiences	32,499
Total number of women in audiences	47,876
Total number of boys over sixteen years	19,408
Total number of girls over sixteen years	20,969
Total number unclassified	1,768

When possible, certain films were used to illustrate the lectures. The following table will show what films were used, the number of times shown and the approximate total attendance. It will be seen that the "End of the Road" was used more frequently than any other film. This is due to the fact that it is more suitable than any of the others for a popular audience. The "Gift of Life," the next most popular film is excellently adapted to audiences of either sex but is less satisfactory before a mixed audience.

	Times Used	Attendance
End of the Road	112	48,307
How Life Begins	11	1,980
Gift of Life	72	12,975
Fit to Fight	1	250
Men's Lecture Film	16	5,116
Animated Diagram	15	2,107
Jinks	7	2,975
Totals	234	73,710

Literature

Less literature was distributed during 1921 than in either of the two previous years. This may be due in part to the fact that no new pamphlets were prepared or published during the year. Requests for specific publications were far more numerous than in any previous year. More than 320,000 pamphlets and over a thousand posters were mailed in response to 5,883 requests. Records of seven interesting cases of syphilis were mailed to approximately 2,600 physicians. During the year a letter containing divisional information has been written weekly to the members of the staff, and at the same time opportunity was taken to call attention to interesting articles in the professional journals and occasionally brief extracts of important articles were attached.

PAMPHLETS DISTRIBUTED

Our efforts toward the education of the public to the fact that syphilis, gonorrhea and chancroid are dangerous communicable diseases which destroy the health and jeopardize the life of the infected and their offspring are meeting with gratifying results.

Only the conservative intellectuals look upon the infected as licentious and they usually have specific reservations. A year ago we took as a measure of progress, the observation that syphilis was an interesting topic for discussion before groups of men or women regardless of what was the immediate occasion of their meeting. Our lecturers were invited to appear on programs of medical societies, meetings of the clergy, of labor organizations, chambers of commerce, women's clubs and parent-teachers' associations. We are now assured by many active physicians and particularly those in charge of the clinics that patients seek advice and treatment for syphilis with almost as little hesitation and embarrassment as they do for any other infectious disease. That our literature is being read in the family is attested by the numerous communications we have from parents, particularly mothers. Recently several institutions of higher education have applied for assistance in giving courses of lectures on social and personal hygiene.

Therapy

Three years ago there were but three venereal disease clinics in the State outside of New York city where syphilis was treated by the intravenous method. Aside from a few dermatologists and urologists, there were practically no physicians who would treat syphilis even with mercury or the iodides. Under these conditions it was exceedingly difficult to secure trained physicians to take charge of the work in the clinics and owing to the aversion shared by all physicians to treating the average patient afflicted with a venereal disease it was difficult to persuade men to undertake to learn the work. They feared both social and professional ostracism. Since then the attitude of the profession has undergone a revolution. Public clinics are now being conducted in 36 cities. The men in charge of them are intensely interested in their work and many of them are devoting their entire time to the treatment of venereal diseases.

The activities in the clinics may be shown in brief by the following tabulations:

	SYPHILIS		GONORRHEA		CHANCROID	
	Male	Female	Male	Female	Male	Female
Number of cases continuing treatment on January 1, 1921	847	609	444	66	20	....
New cases added during 1921	1,719	980	1,751	276	62	1
Cases readmitted during 1921	1,350	821	636	93	24	....
Total	3,916	2,410	2,831	435	106	1
Patients discontinuing treatment:						
With permission	795	487	884	238	61	1
Without permission	1,113	616	1,293	86	32	....

Deducting the discharges from the admissions it will be seen that more than 4,000 patients are on the clinic rolls. A portion of these patients have progressed with their treatment to the point where they are instructed to return at intervals of a few weeks or a month for examination but there are attending regularly for treatment a total of 2,805 patients of the above groups.

Treatment Administered

	Syphilis	Gonorrhea	Chancroid	Non-venereal
Male	40,980	27,564	594	6,523
Female	25,747	9,032	16	980

Number of Specimens taken for Laboratory Study with Result of Examination:

	Blood specimens	Pus smears for gonococci	Dark field examinations
Positive	3,287	2,406	46
Negative	5,847	4,615	32

A certain number of patients are treated at the clinics who have urethritis or other affections of the urinary or genital tracts from which the specific organism cannot be isolated or the etiology definitely determined but which probably are due to a previous specific infection. These cases because of their indefiniteness have been grouped under the head of " non-venereal " cases and receive symptomatic treatment. In some instances continuous study discovers the true nature of the disease and the patients are then correctly classified or discharged from the clinic. During 1920 there were 423 cases of this kind admitted by the clinics and 979 during 1921, an increase of more than 100 per cent. The increase was equally distributed among the males and females.

Not all patients coming to the clinics come for treatment directly but a certain proportion of them come only for information. The consultations vary in character. Sometimes the patient seeks advice about avoiding infection from associates; other times it is to determine whether or not they themselves are infected. Not infrequently persons learning as a result of their consultation that they are infected, secure treatment from their family physician or a specialist.

During 1920 there were 475 patients registered for consultation at the clinics while in 1921 there were 719 patients, an increase of 66 per cent.

During the year there were admitted to the clinic 2,699 patients seeking treatment for syphilis and 2,027 seeking treatment for gonorrhea. At the close of 1921 there were receiving treatment at the clinics more than 2,000 syphilitic patients and over 600 having gonorrhea. More than 100,000 treatments have been given these patients during the year which denotes an increase of approximately 35 per cent over last year. Of these treatments 36,596 were for gonorrhea and 66,727 for syphilis; of the latter, more than 28,000 were intravenous injections of arsphenamine representing an increase of 25 per cent over last year. As an indication of the carefulness with which the clinic work is done, it is gratifying to report that not a single serious reaction, has occurred in all of this intravenous medication.

The arsphenamine manufactured by the laboratory was distributed in ampules of 4 sizes, namely, 1.2, 1.0, 0.6 and 0.4 grams respectively. The distributions by months is shown in the table below.

	1.2 grams	1.C grams	0.6 grams	0.4 grams	Total grams
January	126	499	1,105	857	1,656
February	170	305	1,420	765	1,667
March	486	....	1,262	912	1,705.2
April	700	....	1,156	1,108	1,976.8
May	759	....	1,608	1,033	2,288.8
June	452	....	672	749	1,245.2
July	151	....	551	825	841.8
August	150	....	396	386	572.0
September	50	....	176	203	246.8
October	25	....	250	224	269.6
November	....	....	286	178	242.8
December	110	....	224	176	336.8
	3,179	804	9,106	7,416	13,048.8
Reduced to grams	3,814.8	804	5,463.6	2,966.4	13,048.8

The marked decrease in distribution since July 1st is due to the legislative instruction to discontinue supplying the prisons and state hospitals.

But a few years ago the syphilitic seeking treatment was welcomed only by the quack, all other offices being closed to him, but today the physician in his private practice has grown more liberal toward the treatment of syphilis. Following the lead of the clinics and responding to the demand created by our educational work among the laity, the practicing physicians are taking greater pains to diagnose syphilis and when necessary are undertaking its treatment according to the modern methods. This is indicated by an increase in the number of specimens submitted to the laboratories for examination. From all the laboratories in the State there were reported during the latter six months of 1918 a total of 807 positive examinations for syphilis and 115 for gonorrhea while during the year of 1921 there were reported 9,752 positive examinations for syphilis and 3,887 for gonorrhea. During this same year the state laboratory alone examined, for physicians, by the complement fixation method more than 50,000 specimens of blood and over 800 specimens of spinal fluid. Calculating from the reports of cases received during the last three years and that at least two and one-half years are required to accomplish a cure of the average case of syphilis, there must be according to our incomplete records, approximately 30,000 persons receiving treatment in the State, exclusive of New York city, where there must be at least 40,000 more.

Analysis of Notifications

Interesting facts may be learned by briefly studying the records accompanying the notifications of cases observed by the physicians in private practice. Several tabulations have been prepared and are set down below.

I. Distribution of cases according to sex of patient.

	Syphilis	*Gonorrhea*
Male	6,214	2,915
Female	3,538	968
Total	9,752	3,883

The totals will vary because all reports were not complete and the tabulations have been made as complete as possible, and to some of the tables have been added records from cases treated at the clinics.

II. Distribution of cases according to sex and color.

	SYPHILIS			GONORRHEA		
	Male	Female	Total	Male	Female	Total
White	5,843	3,311	9,154	2,915	968	3,883
Black	371	227	598	91	27	118
Total	6,214	3,538	9,752	3,006	995	3,901

III. Distribution of cases according to disease and age of patient at time of submission of first specimen.

	SYPHILIS		GONORRHEA	
	Number	Percentage	Number	Percentage
Under one year	56	0.58	37	0.94
1–9	154	1.60	179	4.55
10–14	162	1.70	58	1.47
15–19	467	4.90	548	13.82
20–24	1,561	16.40	1,222	31.18
25–29	1,634	17.10	920	23.40
30–34	1,446	15.12	487	12.40
35–39	1,322	13.80	249	6.35
40–44	1,622	17.00	118	3.00
45–49			54	1.37
50 plus	1,126	11.80	60	1.52
Total	9,550	100.00	3,932	100.00
Not stated	202		67	
Total	9,752		3,999	

IV. Distribution according to sex, marital condition and disease.

	SYPHILIS		GONORRHEA	
	Male	Female	Male	Female
Single	2,797	881	1,846	517
Married	2,930	2,337	796	367
Widowed	201	216	33	19
Divorced	16	31	5	3

V. Distribution according to residence of patient.

	SYPHILIS		GONORRHEA	
	Male	Female	Male	Female
Urban	4,768	2,762	2,404	759
Rural	1,419	758	508	209
Out of State	27	18	3	....

Since the population is about evenly divided between the rural and urban districts it is necessary to explain that laboratory and clinical facilities being much more accessible in the vicinity of cities may account in a measure for the apparent difference of distribution. It is interesting to note that the ratio between the sexes seems not to have been affected by residence. Of those infected with syphilis 23 per cent of the males and 21.5 per cent of the females came from the rural districts while of those infected with gonorrhea 17.5 per cent of the males and 21.5 per cent of the females were outside of the cities.

VI. Distribution of cases according to stage of the disease.

	SYPHILIS		GONORRHEA	
	Male	Female	Male	Female
Acute	1,395	644	1,685	395
Chronic	2,605	1,273	287	89

The stage of the disease when the first specimen is submitted varies considerably according to the disease. Of the cases of syphilis 34 per cent are acute while 85 per cent of the gonorrhea cases are acute. In 1920 the number of acute cases of syphilis was 2 per cent greater than this year regardless of the fact that the number of cases reported in the two years is about the same. Sex has no influence on this table; practically the same proportion of acute cases came from each sex.

In 3,877 of the cases of syphilis or about 40 per cent of all reported, the period of time elapsing between the exposure to infection and the submission of the first specimen was stated. It will be seen from the table below that about 60 per cent of the syphilis cases did not seek medical attention within the first year after the inoculation. Twelve per cent sought advice between the 5th and 9th year after infection, 21 per cent ten or more years later, while 7 per cent waited more than twenty years.

VII. *Showing the interval between the date of infection or detection of initial sore and the time of submitting the first specimen from cases of syphilis.*

	NUMBER OF CASES	PER CENT
Less than 1 year	1,570	40.55
More than 1 but less than 2 years	380	9.80
More than 2 but less than 3 years	314	8.10
More than 3 but less than 4 years	200	5.20
More than 4 but less than 5 years	130	3.40
Between 5 and 9 years, inclusive	471	12.00
Between 10 and 14 years, inclusive	350	9.00
Between 15 and 19 years, inclusive	185	4.80
Between 20 and 29 years, inclusive	228	5.90
Between 30 and 39 years, inclusive	37	0.95
40 plus	12	0.30
Total	3,877	100.00

Distribution of Arsphenamine

For the most effective treatment of syphilis certain forms of mercury and arsenic are necessary. The mercury preparations are comparatively inexpensive and readily obtainable by the average physician or institution, but the arsenic preparations on the other hand are very expensive (although it is claimed they can be manufactured for much less than they cost on the market) and satisfactory products are produced by only a few manufacturers. It is not safe to use any preparation that has not been examined and approved by the United States Public Health Service Laboratory. The State laboratory for a time manufactured arsphenamine which was approved by the service as a very superior product. During the last three years we have distributed among the clinics, prisons, reformatories, orphanages and State hospitals more than 33,000 grams of arsphenamine to be used in treating indigents or their inmates who are wards of the State.

The benefit to the State from the careful use of this drug is so great that any attempt to estimate it would be in vain. Those treated are but a fraction of those who are in need of treatment but who will never get it because of their inability to spare the cost. In the meantime their disease will progress with the probability of eventually making them wards of the State or a charge upon their communities, and most likely; before that stage is reached, they will have been instrumental in bringing into the world some infected offspring who will be doomed to an early death or to a life of misery. The number of requests for treatment by those who have learned that they are infected but are not near to a clinic and cannot afford to pay a physician for their treatment is increasing. Not a few times the infected are heads of families and are aware of the menace they are to their wives and children. There should be at our disposal a supply of arsphenamine from which we could supply a local physician the amount required to treat such cases.

Hospital Survey

A questionnaire was sent to the hospitals in the State in 1916 by Wood, making inquiry concerning their desire to admit or treat syphilitic patients and it was found that about 45 per cent were willing to admit cases. During the past year a similar questionnaire was submitted by this division and responses were received from 212 hospitals in which 146 or 69 per cent signify a willingness to treat chronic cases of syphilis, while 84 or 40 per cent will admit acute cases. The number willing to take cases of gonorrhea is not quite so great, 67 per cent will admit chronic cases and 32 per cent will admit acute cases. Of those hospitals conducting out-patient dispensaries, 56 per cent will treat cases of syphilis and 51 per cent cases of gonorrhea in their dispensaries. This data indicates that hospitals have during the last 5 years increased their facilities for the care of the venereal patient by more than 50 per cent. The presence of syphilis in a patient is often not suspected until a test of the blood reveals it. Realizing this many clinicians have adopted the practice of making a test of every patient's blood as a matter of routine. Inquiry was made of the hospitals to ascertain how many had adopted a similar practice. A summary of the hospital survey follows:

	Up-State	New York City	Total
Number of hospitals	147	64	211
Total beds	11,622	21,632	33,254
Free beds	8,325	18,806	27,131
Private beds	3,297	2,826	6,123
Venereal clinic	12 (8%)	27 (42%)	39 (18%)
Acute syphilis	65 (44%)	18 (28%)	83 (39%)
Chronic syphilis	113 (77%)	32 (50%)	145 (69%)
Acute gonorrhea	47 (32%)	19 (30%)	66 (31%)
Chronic gonorrhea	113 (77%)	27 (42%)	140 (66%)
Have maternity ward	103 (70%)	41 (64%)	144 (68%)
Admit venereal obstetrical cases	72 (49%)	12 (19%)	84 (40%)
Proportion of hospitals having maternity wards and performing Wassermann tests on maternity patients	(70%)	(29%)	(58%)
Making routine Wassermann:			
On free patients	24 (16%)	29 (45%)	53 (25%)
On medical cases	24 (16%)	27 (42%)	51 (24%)
On surgical cases	22 (15%)	25 (39%)	47 (22%)
On obstetrical cases	28 (19%)	23 (36%)	51 (24%)

Medical Follow-up

A medical follow-up program is being developed at the various clinics. Its aim is to keep the patients interested in their treatment but also includes inspection of family contacts with complete medical examination where indicated and feasible. The importance of the first named object is appreciated by all engaged in the work. It is a very difficult task at times to persuade a man or woman that they are not cured when the initial syphilitic sore is healed but that treatment must be continued until other more elaborate tests give no evidence of the persistence of the disease. Many persons who have thus unadvisedly discontinued their treatment have later in life suffered recurrences of the disease. During the intermission from treatment, which may be

10 or 15 years, the disease has been insidiously developing in the deeper tissues without the patient realizing any change. Such persons often suffer a nervous collapse. A demonstration of this characteristic of the disease was recorded within the last year in a locomotive engineer employed on one of the large railroads of the State. He was apparently in the best of health but ran by a signal set against him and could give no satisfactory explanation for his action. A careful medical examination was made of him including a test of his blood. Nothing definite was found except a positive reaction to the complement-fixation test. He was relieved of his highly responsible position but retained as an employee. Within six months however his disease had totally incapacitated him and in another two months he died in a state hospital.

That many cases of unsuspected syphilis may lurk among the family contacts of the infected was demonstrated by the work in which this division had a part which was reported by one of the state hospitals about a year ago. Among the family contacts of 75 syphilitic insane 50 other cases of syphilis were established. Further proof of the significance of this report was shown by investigations undertaken by this Division of the families of two groups of children. The first group had congenital syphilis as indicated by the reaction of their blood and the histories collected. Blood specimens from their family contacts reacted positively to the complement fixation test, indicating the presence of syphilis, in 82 per cent of the examined. From the second group of 263 children whose blood reactions were neither frankly positive nor definitely negative, 173 relatives were examined and 13 per cent of them found to have syphilis. In this group 24 per cent of the mothers and 14 per cent of the fathers examined were found infected.

The physicians in charge of the clinics report similar findings in the follow-up work of their patients. Examination of family contacts is perhaps one of the most important undertakings of the year.

Ophthalmia Neonatorum

If a woman who has had gonorrhea becomes a mother it sometimes happens that the child is inoculated with the germs as it is being born. The seat of infection is usually in the infant's eyes. They become acutely inflamed and overflow with a purulent discharge. Unless they are immediately and scientifically treated blindness will result. Figures prepared by the New York State Commission for the Blind show that 24 per cent of the blind in the State are so because of opthalmia neonatorum. The gonococcus is not the only germ that causes sore eyes in the infant but it is by far the most dangerous. Opportunity was had to investigate a certain number of cases of opthalmia neonatorum during the year and it was found where laboratory examination had been made to determine the cause that 11 out of 12 cases or 92 per cent were due to the gonococcus. Prospective mothers must be warned of this danger and physicians should be requested to instil a prophylactic into the eyes of every child at birth as a matter of routine because the prophylactic can do no harm and may destroy germs where their presence is not even suspected.

In summarizing the report for the year the following observations would be marked:

1. Extension of educational work to the rural districts.
2. Great increase in number of physicians treating venereal diseases.
3. Marked increase in the activities of the clinics.
4. Developing need for free distribution of arsphenamine.
5. Gratifying increase in the number of hospitals willing to admit venereal disease patients.
6. Striving for prolonged treatment.
7. Significance of medical and serological examination of family contacts of all patients.
8. Prophylactic measures to prevent opthalmia neonatorum.

DIVISION OF COMMUNICABLE DISEASES

DIVISION OF COMMUNICABLE DISEASES

HERMANN M. BIGGS, M.D., *Commissioner of Health, Albany, N. Y.:*

SIR.— I have the honor to submit the attached report of the Division of Communicable Diseases for the year 1921.

Respectfully,

EDWARD S. GODFREY,
Director.

March 17, 1922.

The year 1921 was chiefly remarkable from the standpoint of communicable diseases, for the extensive prevalence of poliomyelitis during the summer and fall, more cases having been reported in 1921 than in any year of record except 1912 and 1916. The total cases reported for the State exclusive of New York City was 565 of which 464 were reported in the months of August, September and October. This unusual prevalence began to be noted in the latter part of July and a warning was issued at that time.

The epidemic centered in the city of Utica, Oneida county, from which 88 cases were reported. The rest of Oneida county reported 75 cases and 37 cases occurred in Herkimer county within 30 miles of Utica — most of them within half that distance — so that approximately 35 per cent of all the cases in the State were reported from this area. Contact was established with a fair degree of certainty in some of the rural outbreaks but in the vast majority no data was obtainable tending to establish the mode of transmission. A number of cases occurring outside of Utica gave a history of having been in Utica or of having been in contact with people who had come from Utica within the incubation period. The number of these and the significance to be attached to the statements require further study of the detailed histories which have been obtained.

Eighteen cases were reported from Syracuse during the latter half of September and the month of October. But one case has been reported from Syracuse during the year until this small but sharp outbreak occurred. The State fair had been held the week before the outbreak began. Ten cases were reported from the town of Hempstead, Long Island, in August, September and October, the greatest number in any one municipality other than Buffalo and those places already mentioned. In all, 255 towns, villages and cities reported one or more cases as against 49 municipalities reporting cases in 1920. The age and sex distribution of the cases were as follows:

Age Periods	Total	Male	Female
Under 1 year	24	14	10
1 year	65	32	33
2 years	60	32	18
3 years	37	20	17
4 years	53	25	28
Total under 5 years	239	123	116
5 years — 9	131	75	56
10 years — 14	80	49	31
15 years — 19	46	30	16
20 years — 24	31	18	13
25 years — 29	10	3	7
30 years and over	24	19	5
No age stated	4	3	1
Total	565	320	245

There was a marked increase in the number of typhoid cases as compared with the last two years — 2,150 as against 1,725 in 1920. The counties with the highest morbidity rates were St. Lawrence, Chemung and Seneca. The rates of the first two named were due to well defined outbreaks, that of Seneca county to an unusual number of so-called sporadic cases, an aftermath possibly, of the 1920 outbreak in Seneca Falls. Putnam county reported no cases during the year.

There were sixteen outbreaks of ten or more cases and nineteen less extensive ones. Outbreaks of special interest were those in Baldwinsville, Onondaga county, twenty-one cases, March and April, due to milk infection traced to a carrier on a dairy farm; Syracuse, between ninety and one hundred cases, August and September, infection transmitted through milk traced to an incipient typhoid case supplying milk to a Syracuse dealer; Elmira, thirty-three cases, October, transmitted through milk traced to "walking" case on dairy farm; Gouverneur, between eighty and ninety cases during September and October, transmitted through well water, infection probably from a privy on the premises or through a sudden rise in a grossly polluted creek which overflowed its bank so that the stream flowed alongside the well; Beacon, outbreak in May and June, another in the same city in November transmitted through milk supply infected by a carrier. This carrier was discovered at the time of the spring outbreak and was permitted to live on the farm with the understanding that he would not engage in any way in handling the milk. Being short of labor in the fall he commenced milking and the second outbreak followed. The sale of his milk has been prohibited.

In none of the milk borne outbreaks above mentioned, nor indeed in any that have been reported to the Department this year was the milk pasteurized.

In order to determine the frequency in which pasteurized milk has been responsible for outbreaks of communicable diseases the Division circularized health authorities throughout the United States in an effort to learn of such outbreaks. The result of this inquiry is to be embodied in an article for publication.

The seasonal prevalence of this year's typhoid was somewhat remarkable since although the number of cases for the first quarter was the highest in four years, the number for the succeeding four months were almost as much lower. August was the lowest on record, except in 1920, its excess over that year being due solely to the Syracuse outbreak. September was the lowest on record, but in October the number exceeded that for any October since 1913 and November and December were the highest in five years. With the exception of the extensive outbreaks in Gouverneur and Elmira these cases occurred either sporadically or as small outbeaks of from five to fifteen cases. The number of foci was much greater than for the preceding year during these months, the increase in rural foci being particularly marked. For the year, however, typhoid was reported from only fifty-nine more districts than in 1920 — 495 in 1921 and 436 in 1920.

It is believed that the factor principally responsible for the morbidity increase was the abnormally dry weather that prevailed in many sections of the State. This resulted in many usual sources of water supply (wells, ponds or streams) becoming inadequate with a consequent resort to doubtful sources. So far as public water supplies were concerned the activities of the division of sanitation unquestionably prevented a very much higher incidence than we have had. But there was no such careful supervision over the wells resorted to by individuals and it seems probable that many cases owed their infection directly or indirectly to wells. The typhoid increase for 1921 was by no means confined to New York State. According to the Bulletin of the Metropolitan Life Insurance Company a marked increase was noted in the States of New Jersey, Illinois, Pennsylvania, Ohio, New York, North Carolina, Maryland, Georgia, Indiana, Alabama, Kentucky and Kansas. A number of explanations have been presented for this increase but none seem as plausible as that given above.

Six outbreaks of diarrhea came to the attention of the Department during the year although scores of them undoubtedly occurred. As has usually happened the outbreaks had subsided by the time they were reported. In two outbreaks, however, fecal and blood specimens were obtained from some of the later cases and fairly good epidemiological data secured. In both, the source of the trouble was quite clearly the drinking water supplied to the patrons of summer resorts.

The Department is very anxious to pursue such investigations further and to that end the Public Health Council has made such outbreaks reportable by health officers. Success will depend largely on the vigilance of the health officers in discovering outbreaks early and on their promptness in reporting them to the department.

Early in the year our attention was called to the prevalence of epidemic of hiccough in Chenango county. An epidemiologist of the Department found upon his arrival that the epidemic had subsided some two weeks previously, but from descriptions of the cases by local physicians he was led to believe that it was epidemic jaundice which had been prevailing. The symptomatology as given in the report of the epidemiologist corresponded quite closely with that of *spirochetosis ictero-hemorrhagiac* as described by Inada, Stokes, Ryle et al, except in its severity. No deaths had occurred in approximately one hundred and twenty cases, and the febrile stage was neither so marked nor so prolonged. The sanitary supervisors were at once informed of this outbreak and of the laboratory specimens which should be submitted from cases in the event an outbreak should come to their notice.

No further outbreaks were reported until the middle of December, when two of the sanitary supervisors simultaneously reported outbreaks in their respective districts. These were followed shortly by reports from a third sanitary supervisor and upon the matter coming to the attention of the Commissioner he directed that a thorough investigation should be undertaken. This investigation was under way at the close of the year. Every physician in the State has been circularized requesting him to report to the Department immediately cases occurring in his practice and it is hoped that material may be thus obtained which will result in establishing the identity of the disease and the method for its control.

Special Investigations

Other unusual investigations were one of apparent ice cream poisoning in Suffolk county which attacked 36 out of 40 boys in camp there and an investigation of suspected food infection in Port Washington. No definite laboratory findings were obtained in either instance.

Only two scarlet fever epidemics are worthy of special mention. One occurred in Wellsville, Allegany county from which place 37 cases were reported during the month of February. The outbreak was referred to Dr. J. J. Mahoney, sanitary supervisor, and with the assistance of one of the State nurses was quickly brought under control. The other was in the village of Ossining early in October, when approximately twenty cases suddenly developed on one milk route. The cases were widely scattered and it was impossible to account for this sudden increase on any other hypothesis than that of milk borne infection.

During the holding of children's consultation clinics in Schoharie county in 1920 an unusual number of goitre cases were discovered. Investigation later disclosed that it was endemic in one section of the county. Efforts were thereupon made to uncover other foci, one result of which was the discovery that numerous cases of goitre existed in a circumscribed area in Rockland county and that the disease was very prevalent throughout Cortland county. Surveys were begun in these counties and an epidemiologist was assigned to investigate; the work, however, was interrupted by the outbreak of poliomyelitis, necessitating his services elsewhere. A nurse was assigned to continue the investigation. The data so far received has not yet been collated.

Smallpox

Smallpox was reported from 99 foci in the State during 1921 as against 65 for the preceding year. The total was 602 as compared with 281 for 1920. The disease was quite prevalent during the first half of the year, 86 per cent of the cases occurring during the first six months. Forty-seven cases were reported from St. Lawrence county and 54 from Carthage, Copenhagen and the surrounding rural districts. Sixty-nine cases occurred in the town of Georgetown, Madison county, in May and June and 82 in Geneva and the adjacent town and village of Phelps. Moravia and the adjacent rural districts reported 28 cases, Seneca Falls and vicinity reported 34 and 33 cases were notified from Cambridge, Washington county, Hoosick Falls, Rensselaer county and their environs. The largest outbreak of the year occurred in the adjoining cities of Tonawanda and North Tonawanda, 37 cases in the former, 64 in the latter.

The story of these outbreaks is a rather monotonous reiteration of mild cases, undiagnosed or unseen by a physician, coming in contact with many people in unvaccinated communities, smouldering for weeks or perhaps months until some case of moderate severity resulted in a correct diagnosis. Only then would the search for missed cases and contacts begin, isolation and vaccination be instituted and the disease brought under control. It will be noticed that all of the outbreaks occurred in small cities, villages or rural towns, none of which are vaccinated unless it should be as a result of a smallpox outbreak. In the nine first and second-class cities of the State, where vaccination is a prerequisite to school attendance, no outbreaks occurred and the disease rate for the year was only one-thirteenth of that elsewhere in the State, exclusive of New York City. The vaccination histories of these cases is given in the following table:

	Number	Per Cent
Total	602	....
Vaccinated within 7 years	21	3.5
Vaccinated more than 7 years previously	35	5.8
Never successfully vaccinated	466	77.4
History not obtained	80	13.3

There were 19,765 vaccinations reported to the Department during the year of which 15,599 were successful and 1,486 unsuccessful. Thirty per cent of these were reported from second-class cities.

The disease rates for scarlet fever, diphtheria and whooping cough were all higher than they have been for many years. The highest diphtheria case rate is to be found in Onondaga county, due principally to the extensive prevalence of the disease in Syracuse, although other nearby towns and villages, especially Solvay, also suffered heavily. Major outbreaks were noted and investigated in Auburn and Ithaca. The epidemic which had prevailed in Buffalo for almost three years declined during the spring and summer and failed to return to its former proportions in the late months of the year.

Sanitary Supervisors

The work of the sanitary supervisors during the year was a further demonstration of the interest and enthusiasm that has come to be characteristic of their work. Despite the fact that one of their number was incapacitated for nearly three months by reason of illness, the total number of hours devoted by them to their work was only 116 less than in 1920, being 33,857 as against 34,873. The hours in travel exceeded that of 1920 by 736, 9,970 as against 9,234. They made 661 visits on account of communicable diseases and over 100 outbreaks were investigated. They had 641 interviews with public health nurses; conferred with 307 town and village boards; held 1,080 miscellaneous conferences, the latter including district conferences with health officers in all the sanitary supervisor districts, except two; attended 92 medical society meetings, 172 meetings of other organizations; gave 322 addresses; investigated 112 complaints and effected 19 consolidations of local health districts. Two consolidations were discontinued, one by an act of the legislature and the other upon the petition of the local authorities.

The most pronounced increase in any class of work over the preceding year was the attendance at clinics, 409 as against 242. Children's consultations under the auspices of the Division of Child Hygiene were held in eight of the sanitary supervisors' districts. The supervisors gave assistance in examining at these clinics, not only in their own districts, but in those of other sanitary supervisors, assignments being made from this Division. Besides the above, children's clinics were held under local auspices in several of the supervisors' districts, the sanitary supervisor arranging for the clinics and usually assisting in the examinations.

Primary district reports were received from 1,147 of the 1,326 local primary districts in the State. These reports are being tabulated and will serve as a basis upon which progress may be measured.

All but eight of the new health officers appointed during the year were visited by the sanitary supervisors. The eight unvisited were all appointed during the closing months of 1921.

There were 640 telephone conferences held besides 393 miscellaneous duties performed, which are not classifiable under the above headings.

Post-graduate courses under the direction of the sanitary supervisors were conducted in connection with the Albany Medical College, Cornell University at Ithaca and Syracuse University. Forty-three students enrolled in the classes.

Summary of Clerical Work — 1921

Number imported infection blanks received (Part I)	295
Number imported infection blanks received (Part II)	133
Number follow-up letters sent to health officers	357
Number follow-up letters sent to sanitary supervisors	85
Number dictated communications (including telegrams)	7,295
Number reciprocal blanks received	44
Number reciprocal blanks sent	54

Diphtheria

Number positive laboratory reports received	11,316
Number first notices sent to health officers (unreported cases)	493
Number answers received	370
Number second notices sent to health officers	117
Number remaining	59

Typhoid Fever

Number positive laboratory reports received	847
Number first notices sent to health officers (unreported cases)	183
Number answers received	136
Number second notices sent to health officers	44
Number remaining	21
Number cards punched for tabulating machines	66,613

Report of Health Officers' Work

Average number of districts for year	1,281
Average number of vacancies for year	29
Average number of districts delinquent on the 10th	328
Average number of districts delinquent on the 15th	211
Average number of districts delinquent on the 31st	69
Average number of health officers for year	951
Average number of health officers delinquent on the 10th	251
Average number of health officers delinquent on the 15th	158
Average number of health officers delinquent on the 31st	50
Suggestion sheets sent to health officers	*305
First delinquent notices sent to health officers	*1,300
Second delinquent notices sent to health officers	*586
Packages of health officers' reports sent to S. S	*108
Delinquent notices to city health officers	*24
Deaths from communicable diseases carded and records searched for communicable disease reports	†3,166

Telegrams received from dairy farms:	
Scarlet fever	143
Diphtheria	51
Typhoid	24
Smallpox	5
Poliomyelitis	18
Streptococcus	1

Total number of communicable diseases reported and tabulated by municipalities in weekly reports	109,170

Letters Relative to Deaths from Communicable Disease — Cases Unreported

Sent to health officers	‡202
Received from health officers	‡145
Sent to physicians	‡133
Received from physicians	‡85

DIVISION OF LABORATORIES AND RESEARCH

DIVISION OF LABORATORIES AND RESEARCH

HERMANN M. BIGGS, M. D., *Commissioner, State Department of Health, Albany, New York.*

DEAR SIR.— For the Division of Laboratories and Research the year 1921 has been characterized by retrenchment, consolidation and standardization. No new activities have been undertaken; one important branch, the production and free distribution of arsphenamine, has been discontinued. To the effectiveness of this consolidation the revision of the budget, which the legislative committees suggested last year, making maintenance and operation one item, segregating personal services into groups and providing adequate sums for temporary services and contingencies, has contributed more than anything else. This classification has made the appropriation flexible to meet emergencies. It has eliminated to a large extent the serious labor turnover of the past three or four years, has effected a saving of at least $20,000, and has stimulated the spirit and morale of the entire staff.

There are many noteworthy features in every department and general progress throughout the laboratory to be recorded, with one exception. The housing of work of such vital importance to the state stands in striking contrast to all else. The one building suited to laboratory work is now overcrowded well beyond the point of safety; the other buildings on Yates Street and at the farm are a disgrace to any institution and a constant menace, and have been condemned in scathing terms by the federal authorities.

Work of the Assistant Director Through the work of the Assistant Director, Dr. Paul B. Brooks, the cooperation of the laboratory with the other divisions of the department and with the local health officers has been improved. The operation of laboratory supply stations has been made more effective, local laboratories have been established, and the laboratory field investigations have been more satisfactorily conducted. He has taken more active supervision of the courses of instruction in public health and of the practical training in laboratory work of volunteers and visitors from other states and foreign countries. This practical training of expert technicians, bacteriologists, and directors of laboratories is a most important work which in many ways will, year by year, not only redound to the credit of the laboratory but will strengthen and improve the standards of laboratory service throughout the State.

Antitoxin, Serum and Vaccine Laboratories

The antitoxin, serum and vaccine laboratories have demonstrated the value and economy of maintaining an adequate staff. For the first time in seven years, this staff has been able to carry on the routine work and study a few of the more important problems which already have led to improvement in methods and have lowered the cost of production. The discontinuance of the production and free distribution of arsphenamine is to be regretted, but, with insufficient appropriations, the work could have been carried only at the sacrifice of all other branches of the laboratory.

Diagnostic Laboratories

Only a moderate increase in the number of specimens examined is shown in the tabulated reports of the diagnostic laboratories. On the other hand, field investigations and various emergencies which have arisen, interrupting the routine work, have broadened the field of efficient service which the laboratory renders and have, furthermore, contributed greatly to the organization of the laboratory service of the state as a unit. The staff is scarcely adequate, and should be increased to meet all emergencies without interrrupting the work of other departments of the laboratory.

Branch Laboratory in New York City

During the year the Branch Laboratory in New York City, under the direction of Dr. Noble, has been brought into closer touch than hitherto with the central laboratory in Albany. For the past three years excessive labor turnover, a numerically inadequate staff and overcrowded rooms have made it impossible to maintain a satisfactory standard in the diagnostic work done in this branch. A new building, however, and an increase in the staff will not only go far toward remedying present conditions but will also provide facilities for study and research.

Water and Analytical Chemical Laboratories

An increased number of samples of water was examined during the year for health officers and for the Division of Sanitation, on account of the difficulties caused by limited rainfall. There is still need for more efficient operation of water sterilization and purification plants. By more frequent examinations and tests of the efficiency of these plants the laboratory can render distinct service.

The analytical chemists are called upon for an increasing number of special analyses, and, within the laboratory, for expert advice as to equipment and supplies in all branches of the work. Mr. Wachter has rendered valuable assistance to the Director by supervising all of the new construction and installation of equipment.

General Service Units

Of the general service departments, the office has approached most nearly its complete plan of organization, and is now in a position to study critically the suggestions made by the examiners of the Board of Estimate and Control.

The department for the preparation and sterilization of glassware and media has been completely reorganized during the year and substantial economies effected; unfortunately the working space is already overcrowded and the equipment far from complete.

Library and Scientific File No one thing has contributed more to the upbuilding of the laboratory than the establishment of the library and of the scientific file. Although working under the handicap of inadequate staff and an accumulation of incomplete work, this unit has during the past year been more effective than ever before. The scientific file has at last brought together all of the scientific investigations of the laboratory in available form for reference or publication, and is a record of very great value. Without the assistance of this unit, it would be impossible for the Director or the heads of departments to conduct the researches of the laboratory.

Research During 1921, progress has been made in nearly all of the research problems of the laboratory. Several noteworthy studies have been published; the results of others have been incorporated in the standard methods and their value is shown in the character of the routine work. The research activities of the staff as a whole — the study of practical problems in the improvement of the routine work — have been stimulated by the completion of the standard methods which have been under way since the reorganization of the laboratory in 1914. A clearer conception of scientific approach and of methods of study has generally developed and attention has been focused upon practical results. In consequence, many economies have been made possible and unnecessary work eliminated.

Special mention should be made of the discovery of the inhibitory action of bacterial culture products on phagocyting leucocytes in the course of the work of Miss Ella N. Hoppe; and, in that of Miss Ruth Vories, the observation that the leucocytes have apparently no action on the true toxins of the diphtheria and tetanus bacilli. The observations of Mr. Frank Maltaner and Miss Elizabeth Johnston on the phenomenon of conglutination, first reported by Bordet, are also important. The complement fixation test promises to be of great practical value as a diagnostic aid not only in cases of human tuberculosis but also in testing cattle. A brief report on the new methods which have been adopted for the purification and concentration of antigens for this test has been published.

Educational Activities The members of the staff have been encouraged to attend meetings, to visit other laboratories and to take advantage of every opportunity for broadening their culture and gaining new knowledge or points of view through contact with persons engaged in similar work. The worker derives great benefit and the state gains much in service. Members of the staff have assisted in twelve courses of instruction in public health and in the training of three persons sent us by the Federal Board for Vocational Training. One hundred and seventy visitors from sixteen states and twelve foreign countries have inspected the laboratory, several of whom have remained for periods of from two weeks to eight or nine months.

The critical survey instituted by Governor Miller and the Board of Estimate and Control has been of incalculable value to the Director and his staff. The examiners made a thorough and painstaking study with the sincere purpose of ascertaining the facts. It was a difficult undertaking for them and it was impossible to gather all the significant facts, but the conclusions were so conservative as to be helpful and stimulating to a further study by the staff of the questions suggested in the examiners' report.

Respectfully submitted
AUGUSTUS WADSWORTH
Director

ALBANY, *January* 23, 1922

Field Activities and Correlation With Other Divisions and Agencies

PAUL B. BROOKS, M. D., *Assistant Director*

The duties of the Assistant Director during 1921 have not differed materially in character from those mentioned in his report for 1920. In order to indicate progress in connection with activities referred to in that report, its sequences are continued here.

That the number of local laboratories is progressively increasing and standards improving is indicated by the fact that our records show ninety-four laboratories approved for public health work at the close of 1921, as compared with sixty-seven in 1920 and thirty-three in 1919.

During the year two new county laboratories have been approved and are in operation, while in three other counties boards of supervisors have voted to provide county service and have made appropriations more or less adequate for the purpose. In another county a laboratory which had not been approved for two years has been established in new quarters with new equipment and necessary help.

The last legislature incorporated in the Insanity Law a paragraph authorizing superintendents of state hospitals for the insane, having approved laboratories, to enter into contracts with counties or municipalities to furnish laboratory service.

St. Lawrence county, one of those referred to above, is the first to take advantage of this provision, having contracted for county service with the state hospital at Ogdensburg.

In the city of Utica a consolidation has been effected between the city and state hospital laboratories, which should react greatly to the advantage of service in the city, and which suggests the possibility of future provision for service for the entire county.

The board of health of one third class city maintaining a laboratory for milk work alone has voted to increase the scope of work done, but has been unable to find a competent bacteriologist at the salary provided. One third class city has contracted with an approved hospital laboratory for municipal service. A number of existing laboratories, some in large and progressive municipalities, have been working constantly at a disadvantage on account of inadequate appropriation. No opportunity has been lost to bring to the attention of local officials the economy, from a public health standpoint, of making adequate provision for laboratory service.

Late in the year the occurrence of outbreaks of infectious jaundice offered an unusual opportunity for investigation of the disease. Within a few days, in addition to the establishment of a state research unit in the central part of the state, it was possible to enlist the services of sixteen local laboratories situated at strategic points.

Following page 48 is shown a chart giving a list of local laboratories approved for public health work, and indicating the kinds of work for which each is approved.

At the close of 1921 there are two hundred and four laboratories registered in accordance with the requirements of chapter 411, Laws of 1917, as amended by chapter 269, Laws of 1921. All laboratories within the state engaged in handling or cultivating live pathogenic organisms are now required to register with the State Department of Health under this act.

Two hundred and one district laboratory supply stations have been established, covering the entire state outside of New York City. From the fact that relatively few complaints are received, it would appear that the district system is functioning satisfactorily from the standpoint of health officers and other physicians. Since many districts have but recently been organized, it is still too early to judge as to relative economy, as compared with the former system of distribution.

Some time ago the writer devised a compact box of diagnostic outfits, designed to be carried in the handbag of the practicing physician. Distribution of these has recently been begun and already many commendatory letters have been received.

Some progress has been made in the direction of promoting popular education regarding public health laboratory work and its value. An exhibit prepared for use in connection with the annual meeting of the American Public Health Association in New York City, was viewed by a large number of people. Stereopticon slides for popular lectures have been completed and are ready for use.

Weekly interdivisional conferences, at which the writer has presided, have been continued and have made possible a much more satisfactory coordination of the activities of different divisions than existed before they were undertaken.

The Assistant Director has been in charge of the undergraduate course in public health given to senior students of the Albany Medical College, and has assisted in connection with postgraduate courses given at Albany and at Syracuse. He has given lectures in connection with two nurses' training courses and with public health nurses' institutes held at Syracuse, New York, and Albany. Meetings have been attended and talks have been given on various other occasions.

As heretofore, the administrative activities of the Assistant Director, other than those already referred to, are left to be covered by other reports or by records in the files of the division.

The writer feels that he should not conclude without again referring to the valuable assistance in connection with important field activities and projects rendered by the staff of district sanitary supervisors. Without their active and cordial cooperation much that has been accomplished would have been impossible.

Antitoxin, Serum and Vaccine Laboratories

M. B. KIRKBRIDE

The distribution in 1921 of biologic and chemical products prepared by the State Laboratory has exceeded that of the preceding year. The larger demand is due primarily to the increased use of this service by physicians throughout the state although, in certain instances, there has undoubtedly been some overstocking by newly established district supply stations. This should be overcome, however, as a closer adjustment of supply to demand is effected. While increased production brought further pressure on the already overtaxed accommodations at the laboratory and farm, a numerically adequate staff has enormously facilitated the work and made possible changes and improvements hitherto impossible. More time has been available for experimental studies connected with production and these studies have given added interest and zest to the work as a whole.

Diphtheria and Tetanus Antitoxins, etc.

Approximately 294 million units of diphtheria antitoxin were distributed as compared to slightly more than 227 million units in 1920 while shipments of tetanus antitoxin increased from about fifty-four to over sixty-seven and a half million units during the same period.

Since it became necessary to increase more rapidly the production of these preparations, a part of the old laboratory building on Yates Street was again utilized for stable quarters. We were thus able during the year to make use of fourteen horses and mules transferred from the State Militia and we also obtained through the interest of Major Chandler nine State Constabulary horses. Other exceptionally good horses which were badly needed were available from the same sources, but advantage could not be taken of the opportunity to acquire them on account of the already overcrowded condition of the stables.

The average titre of horses bled for diphtheria antitoxic plasma, as shown by monthly trial bleedings, was 416 units per cc. Three animals exceeded 900 units per cc. The average unit concentration of the antitoxin distributed was 200 units higher than during the preceding year.

Procedures connected with concentration have been improved and simplified, resulting in considerable saving of time, labor and expense in production, as has the adoption of the intracutaneous method for certain tests of diphtheria antitoxic material.

The production of diphtheria and tetanus toxins for immunizing purposes maintained a uniformly high level, none of the routine lots falling below the required standard of toxicity.

Schick Test, Diphtheria Toxin-Antitoxin Mixture The distribution of outfits for the Schick test and diphtheria toxin-antitoxin mixture has increased 50 per cent and 78 per cent respectively. Most of these supplies were taken by Buffalo and Rochester. It is to be hoped that during 1922 more localities will avail themselves of this laboratory service for the active immunization of school children especially those in the primary and lower grades and in institutions.

The value of the Schick test depends upon the accuracy of the outfit and the ability of the physician to perform the test and to correctly interpret the reactions. Further experience confirms the policy of the laboratory in requiring that those obtaining the outfits should be thoroughly qualified to use them. Comparative tests made by Dr. Early have again demonstrated the exceptional accuracy of the outfit prepared and distributed by the State Laboratory.

Therapeutic Immune Serums The distribution of therapeutic serums has increased. Additional horses immunized during the year to a limited number of standard type strains of meningococcus have confirmed the previous findings that a more prompt and higher agglutinative response is obtained by this method than by the former in which fifty or more strains were used.

Bacterial Vaccines Approximately 2,300 more packages of typhoid-paratyphoid and of pertussis vaccine were distributed than in 1920, the increase being chiefly in the latter. There was some decrease in the typhoid vaccine sent out. In anticipation of the advisability of increasing the concentration of pertussis vaccine, special lots containing 4,000 instead of the usual 2,000 million bacilli per cc. have been prepared and sent out during the last two years. The higher concentration has now been adopted for routine production and general distribution will begin in January.

Diagnostic Immune Serums Monovalent agglutinative serums representative of the three main groups of B. dysenteriæ and of the meningococcus Types I, II and III, have been added to the list of diagnostic serums distributed to approved laboratories requesting them. The demand for the laboratory's surplus from laboratories in other states and foreign countries has continued. A large order has been placed by the Rockefeller Foundation for quarterly shipments of material to be used in China. The sales have approximated $2,700 which reverts to the State Treasury. The absence of a federal license still prevents the sale outside of New York State of surplus therapeutic products.

Arsphenamine Early in 1921 the manufacture of arsphenamine on a much larger scale was made possible by the installation of a larger still. The quality of the product also improved. During the first half of the year the amount of arsphenamine produced was thus greatly increased and further purchase of the drug became unnecessary. The equivalent of over fourteen thousand 0.6 grams of laboratory product was distributed between January and July.

After July when funds for carrying on the work were no longer available, the staff was reassigned and production discontinued. It has, however, so far been possible, from the supply on hand, to continue shipments of arsphenamine to localities where complete curtailment would have caused special hardship.

Much credit is due to Mr. Davis and Mr. Roelky and their assistants for the interest and enthusiasm shown in the work under particularly trying conditions at the Yates Street laboratory. Problems connected with chemotherapy will undoubtedly arise in the future. The presence of workers trained in these exceedingly difficult and complicated technical procedures is likely to prove an invaluable asset to the laboratory.

Bacterial Collection The usefulness of a small but comprehensive bacterial collection can hardly be overestimated. Besides acting as a distributing center for cultures, the group having charge of the collection should be prepared to undertake special studies on the identification of new or atypical strains referred to it; it should cooperate in investigations and otherwise assist the workers in this and other laboratories. Since January, when the collection was organized into a separate group in charge of Miss Ingalls, under the immediate supervision of Dr. Sperry, encouraging progress has been made along these lines. New cultures have been added and a careful study made of those already in the collection. The number of cultures distributed has doubled.

In line with these changes the work connected with sterility tests on all biologic products has been made into a sub-group which will be under the supervision of Miss Ingalls. During the year nearly twenty-nine thousand tubes and flasks inoculated with the biologic products were examined.

Farm The immediate supervision of all farm activities directed by Mr. Schadler has been placed under Dr. Griffin. An adequate staff since June, and funds available for the most urgent repairs, have greatly helped in improving conditions. The repairs have included painting the two tenants' houses, shingling, repairing the foundations of the barns, the building of an excellent fence around one of the horse pastures, the construction of a ditch for drainage purposes, grading of roads, etc. An encouraging beginning has thus been made although conditions under which the horses must be kept, bled and injected, remain exceedingly bad and the overcrowding is worse. The new construction that is imperatively needed was given in last year's report.

It became necessary to transfer most of the smaller laboratory animals to the old laboratory building on Yates Street. Here more systematic breeding and care of the animals can be undertaken. While some of the farm crops fell below last year's record owing to weather conditions, production as a whole was approximately the same. During 1920 the farm was able to supply for the first time practically all the green feed required for the smaller laboratory animals. Besides the injections and bleedings connected with production of antitoxins and immune serums, over 700 liters of serum for media were obtained and shipped to the laboratory.

Filling and Boxing of Products The work of the filling and boxing group indicates in a measure the increased output of the department. Approximately 141,000 bottles were filled and 132,000 individual packages prepared for distribution as compared to 103,000 and 93,000 respectively in 1920. Through the diligence of Miss Tegler and her assistants the additional work was accomplished without any increase in staff.

Staff, etc. Dr. Sperry, who was appointed January 1, 1921, has given valuable aid along various lines and is assuming responsibility for many details of administration.

A number of the workers have attended scientific meetings and visited laboratories elsewhere and this privilege has been much appreciated.

During the year there were approximately twenty-two new appointments or assignments to the department and twenty-seven resignations or transfers. The larger number of transfers is due to closing the arsphenamine work. The training of new assistants has retarded investigations in the scientific groups but the increases in the staff have now placed the department in a far better position to carry on the work satisfactorily than has ever been possible.

Duties as secretary-treasurer of the New York State Association of Public Health Laboratories have required considerable time but the contact with workers in other laboratories has been very stimulating and helpful. An abstract of papers and discussions at the meeting held at the State Laboratory in October was prepared for distribution to members of the association.

The routine methods for the department have been or are in process of being rewritten.

Special Studies and Investigations Among the studies completed or in progress the following may be mentioned:

A method for determining by means of the intracutaneous test varying amounts of diphtheria antitoxin present in horse serum, plasma and antitoxin has been developed by Miss Leddon. This method — adequately controlled by the subcutaneous method — is now used for testing all trial bleedings, samples of plasma and experimental fractions and, in certain instances, as a preliminary test on antitoxin. Approximately one-fifth the number of guinea pigs required by the subcutaneous method are used, and all the animals are later available for other purposes.

Eighteen mules belonging to the State Militia were tested for natural antitoxic substance and the results were compared with those of tests on an equal number of horses. The average content was found to be approximately the same. Of the six mules immunized against diphtheria toxin, the serum of all reached a titre above 500 units per cc., two going above 1100 and 1250 units (the highest dilution tested).

Studies have been made by Mr. Wood along different lines connected with the concentration of antitoxins. The work is still in progress but already valuable data have been obtained and certain procedures adopted which have improved and simplified production. The addition of Mr. Murdick to this group in July was of great assistance and has made it possible to push forward investigations long delayed on account of lack of competent assistance.

A comparison was made by Dr. Sperry and Miss Hutton of the actual number of bacilli per cc. in samples of typhoid and paratyphoid vaccines prepared by a federal, a city and a state laboratory. The haemocytometer was used for counting. The vaccines from two of the laboratories showed a much higher concentration than was given on the labels. A further comparison was made by testing the agglutinating titre of serums from rabbits immunized against two of the vaccines, using two methods of immunization for each vaccine. The average titre of the serums from rabbits receiving the vaccine with the highest or the lowest count was approximately the same whichever method was used.

An initial stuy by Miss Hutton of the agglutinative titre of serums from horses immunized against a varying number of strains of the meningococcus has been completed but further tests will be required at stated intervals.

The value for the maintenance of stock cultures of a nutrient gelatin medium described by M. Cobb Worth has been tried for about sixty selected strains by Miss Ingalls. The results to date indicate that the medium will be unusually satisfactory for this purpose.

In conjunction with the preparation of arsphenamine in charge of Mr. Davis a long series of special studies was made on the laboratory product. These included procedures to determine the effect of reactions on toxicity by variations in the amount of alkali added, temperature of the diluent, period of standing before and after alkalinization, etc. A parallel study was made of the hydrogen ion concentration of the solutions.

With a view to its practical application to the Schick test, a study is being made by Miss Dow of the rate of deterioration of diphtheria toxins under different conditions. The work is still in progress.

A number of samples of catgut made by three manufacturers were received from two hospitals for examination. Several of the samples were contaminated.

No summary of the year's activities would be complete without mention of the aid obtained from the library. The library unit as a whole is indispensable to the further development of the work in this department.

Report of the Diagnostic Laboratories

RUTH GILBERT

The activities of the Diagnostic Laboratories have been specially varied and fruitful during the past year. The organization has been improved, standard methods further revised, the scope enlarged, and progress on the task of inspecting and standardizing laboratory work throughout the state has been made; also outside emergency calls have been met. The volume of regular work accomplished has been maintained, and even increased in the case of certain examinations. The increase was most noticeable in the number of throat cultures examined for diphtheria bacilli.

The amount of literature which has been reviewed and of investigation that has been carried on during the year is remarkable in view of the fact that the routine has been heavy and that at different times a number of our workers have been called upon to serve in emergency cases away from the laboratory. All of the research work was undertaken with the purpose of solving actual problems that are met with in our daily work or of improving details of procedure. Not only, however, have the results been of use in our own laboratory, leading to improved standard methods with economy of time and material, but the workers in some cases have been able to formulate these results in order to present them before audiences and to publish them in scientific journals.

Several changes and additions have been made in the routine:

Flagella Stain

Schunk's modification of Loeffler's flagella stain is now being used in all examinations where there is doubt concerning the motility of the cultures.

Endo's Medium

Robinson and Rettger's modification of Endo's medium has been adopted as more satisfactory than Kendall's modification for use in the isolation of organisms of the enteric disease group.

Diagnosis of Chancroid

The method recommended by Teague and Deibert for cultural examinations in the laboratory diagnosis of chancroid has been learned by our workers.

Wassermann Reaction

In the serological diagnosis for syphilis, a fifteen minute period of incubation for the titrations made in the standardization of the hemolytic system has been adopted; and a four-hour period for fixation in the ice box has been adopted for the tests with the cholesterinized antigens. In cases where a doubtful reaction is obtained or where the results of the test do not agree with the clinical findings, results by the ice box method are checked by supplementary tests with a half-hour period of fixation in the water bath at 37° C.

Production of Amboceptor from Mules

Amboceptor for use in the complement fixation test for syphilis has been produced in a mule. A large amount has been prepared using this animal, thus saving the time spent in the immunization of rabbits for the production of amboceptor. As a result of tests which have been made, glycerine is shown to be an effective preservative for amboceptor. All amboceptor is now preserved with 50 per cent glycerine.

Globulin Test Noguchi's picric acid test for globulin in specimens of spinal fluid is being used to confirm the results obtained with the butyric acid test.

Typhus Fever and Infectious Jaundice We are now prepared to make the Weil-Felix agglutination test for typhus fever and to make tests for the Pfeiffer phenomenon with *Leptospira icterohaemorrhagiae* on specimens of blood from suspected cases of epidemic jaundice.

Pneumococcus Type Differentiation The pneumococcus type differentiation has been transferred to our department. Type I pneumococci have been isolated from 21.9 per cent of the specimens examined.

A special effort has been made during the year to secure more satisfactory data with specimens submitted for examination and to have the specimens labeled more carefully. Physicians throughout the state have cooperated well in this matter.

A container for larger specimens of blood for the agglutination test for typhoid has been adopted. We hope with this container to have more satisfactory specimens submitted for examination.

Arrangements are being made to have tubes containing the Loeffler's medium for throat cultures corked. This means should prevent drying for a longer period than the method of sealing now in use.

Apparatus has been purchased for blood chemical tests.

Unusual Specimens Received During the year the laboratory has been called upon to examine specimens from a number of interesting cases. A specimen of spinal fluid was received which gave complete fixation with both anigens used in the complement fixation test for syphilis. A guinea pig inoculated with some of the fluid developed typical tuberculosis. The patient died four days after the specimen was taken. The clinical diagnosis was lethargic encephalitis.

Several gall bladders were sent to the laboratory to be examined for typhoid bacilli. In most cases those found positive contained gall stones. With one exception, the appendix from each case was also sent. In one of these, apparently normal until cut into, a common pin, black from corrosion, was found. Fecal specimens from three of the cases contained typhoid bacilli after the gall bladders had been removed, but only one after several months continues to be positive.

Following a case of diphtheria which occurred among the workers, throat cultures were made from 168 members of the staff. Morphologically typical diphtheria bacilli were found in the cultures from seven of the contacts. Six of these cultures gave the sugar reactions of diphtheria bacilli — all seven proved non-virulent for guinea pigs.

A specimen of discharge from an ear contained diphtheria bacilli. Diphtheroids are so often isolated from this source that the isolation of virulent diphtheria bacilli is of special interest.

In several instances organisms having the typical morphology of diphtheria bacilli in young cultures have been isolated from throat cultures which on longer incubation have coccoid morphology. These cultures have given the sugar reactions of diphtheria bacilli, but produced lesions in animals different from those produced by diphtheria bacilli.

Emergency Calls

During 1921 there have been fewer calls for workers to help those in charge of out-of-town laboratories or to organize a temporary laboratory in connection with emergency conditions. Yet seven members of the diagnostic department helped in two consultation clinics held at Brewster and Jamestown. Workers were sent out in response to emergency calls from Amsterdam, Auburn, Belmont, Geneseo and Olean. On two occasions there was shortage in the staff, and at the other three laboratories assistance was needed to help with the routine work.

Work of Inspecting and Standardizing the Work of Laboratories in the State

The work of inspecting laboratories throughout the state has progressed most encouragingly. Eighty-four laboratories have been visited by members of our department during the year. Valuable data have been gathered and tabulated which will serve as a basis for comparison between the different laboratories. Ninety-four laboratories have been approved. This number is an increase of twenty-seven over that of last year. In general, the directors of these laboratories have cooperated cordially with the State Laboratory in the efforts to standardize the laboratory service throughout the state.

The New York State Association of Public Health Laboratories met during October for an all day session at the laboratory. Enthusiasm was aroused by the papers which were read and the discussions which followed. Five members of the diagnostic staff presented phases of their work. It is planned for future meetings that the diagnostic groups will demonstrate unusual or only slightly familiar technique, and arrange to show interesting slides, smears or other material to the visiting laboratory workers.

Visitors to the Laboratory

During the year twenty persons interested in laboratory work have visited the diagnostic department to inspect the equipment and work — several came from other states or other countries. Visitors who wished to become thoroughly familiar with the methods in use here have remained anywhere from a few days to several weeks or even months.

Investigation and Research

An unusual amount of investigation has been carried on in connection with the daily routine, and the knowledge gained has been applied whenever required to increase the effectiveness of the work in the diagnostic department.

The following papers have been presented by members of the diagnostic department: A comparative study of diagnoses made in various laboratories in New York State; a comparison of the value of 0.6 per cent and 6 per cent salt solution in the glycerine outfits for submitting feces; occasional irregularities in routine virulence tests; lesions resembling tubercles noted in guinea pigs in which no acid-fast bacilli were found; a comparison of icebox fixation with water bath fixation for complement fixation tests with cholesterinized antigen; the use of a 15-minute titration period for the standardization of the hemolytic system in complement fixation tests; a brief study of the influence of bacterial growth on the globulin content in spinal fluids; the relative efficiency of various differential media for the isolation of organisms of the enteric disease group; the use of sterilized cultures for typhoid agglutination tests.

Several additional pieces of investigation now in progress may be mentioned. The frequency of positive agglutination tests on specimens of blood from typhoid and paratyphoid carriers has been studied. We have been interested in noting that the agglutination test has been negative in some cases that have been definitely proven to be carriers.

Cultural work is being done in the hope of obtaining a more satisfactory method for the isolation of gonococci from discharges.

Tests are being made to determine the value of absorbing natural anti-sheep amboceptor from specimens of serum submitted for the complement fixation test for syphilis. A classification of specimens received for this test relative to the source is being kept for the purpose of ascertaining the prevalence of syphilis in different social groups. The results of the tests are also being studied in relation to the clinical histories supplied with a view of determining the accuracy of the complement fixation test in the diagnosis of syphilis.

In considering the reasons why the work of the diagnostic laboratories has, on the whole, been satisfactory, the principal one perhaps is that the per cent of so-called " labor turnover " has been much less during the past year than ever before. No matter how well fitted or experienced workers may be when they enter the laboratory, their first year is largely one of adjustment for most of them. Especially in the case of workers well prepared to be trained, it takes several years before they reach a high degree of usefulness. During 1921 there has been relatively some stability in the personnel of the diagnostic staff, and this fact has enabled us to accomplish a large volume of work.

The library staff and those in charge of the scientific file have been of assistance in connection with our investigations by securing references and criticizing papers that have been prepared for publication.

The opportunity for a number of the workers to visit other laboratories and to meet experts in the line of public health activities has been a great stimulus. Whenever possible, members of the staff are encouraged to take part and to present papers before scientific societies. Several persons from the diagnostic groups have taken advantage of the privilege and have visited other institutions and have attended meetings. The personnel of the various groups is excellent, and we look forward during the coming year to increasing still further the diagnostic service of the State Division of Laboratories.

The Branch Laboratory

WILLIS C. NOBLE

Although located in New York City, the Branch Laboratory does not serve the city; its district comprises the counties of Orange, Rockland, Westchester, Nassau and Suffolk.

Volume of Work

The number of specimens examined shows an increase of nearly 7 per cent over that for the year 1920 (20,134 to 21,477). The total number of tests, however, has fallen from 40,530 for 1920 to 34,194, due chiefly to a change in the method of performing the complement fixation test. An increase of 25 per cent in the number of virulence tests of diphtheria bacilli indicates a growing appreciation on the part of physicians of the significance and value of the test. Although there has been a slight decrease in the number of specimens submitted for the complement fixation test for syphilis (8892 to 8764), the number for 1921 signifies an increase in the service rendered by the Branch Laboratory for a large proportion of the specimens submitted during 1920 were due to the activity of the Division of Venereal Diseases of the State Department.

Public Health Instruction

During the past year the staff has assisted in the instruction of six different classes for health officers, held under the auspices of the University and Bellevue Hospital Medical College, and in the Institute for Public Health Nurses held last June. The assistance given by Miss Thomas and Miss Knacke in this work beyond their regular duties deserves especial mention.

Experimental Work

Miss Kelley has continued her experimental work on the precipitin reaction in the diagnosis of gonorrhea. She began this work more than a year ago, before she joined the Branch Laboratory staff, upon a grant to the University and Bellevue Hospital Medical College by the Interdepartmental Social Hygiene Board.

Changes in the Staff

There has been a labor turnover during the year of 73 per cent, due in part to a desire of some of the workers to pursue advanced courses in university graduate schools; in part to inadequate salaries, especially in the lower grades; to an inadequate staff in general for the amount of work being carried on in the laboratory; and finally to inadequate quarters and laboratory facilities. In February and March, the salary situation became critical. Laboratory apprentices and assistants, junior grade, were receiving $70 and $75 a month, respectively, while outside institutions were offering from $100 to $125 a month for workers of the same grade. In consequence a number of workers were lost, the Wasserman group suffering especially. By the grant of supplementary salaries from the Interdepartmental Social Hygiene Fund, and through the generosity of Dr. Park, who paid other supplementary salaries for a few months, the situation was saved until the new budget became available on July first. Such frequent and numerous changes in the staff necessarily resulted in diminished working efficiency and an exceedingly heavy burden for the few experienced workers remaining, some of whom became ill under the strain. It is confidently hoped that in the coming year conditions will be more favorable and apparently much has already been accomplished in this respect; the salary situation has been remedied in part, but the minimum salary of $75 a month is still below actual living costs and below salaries now paid by hospital, private and medical school laboratories in the city. The addition of six workers to the former staff of eleven, which was made in September and October, has aided through allowing more time for the interpretation of results, for the study of problems arising in the work, and for study and reading by the workers; the new laboratory with its additional space, so sorely needed, will make conditions livable for the staff and will permit of better and more efficient organization. The present staff is the strongest in capable and experienced workers which the Branch Laboratory has ever had.

Detail of Workers to the Central Laboratory

In September and October, three workers were detailed for tours of duty of about two weeks at the Central laboratory. These were most profitable to them, and have aided in bringing about closer cooperation between the workers of the two laboratories. It is, however, unfortunate that expenses, except for traveling and one day at Albany, must be borne by the worker.

New Laboratory Building

By far the event of greatest moment during the year has been the erection of a new laboratory building. In July work was begun by the University and Bellevue Hospital Medical College, at 339 East 25th Street, on a new wing of the college building, to be seven stories high and to be used entirely for public health work. Two stories will be given to class rooms, and five stories — approximately 6,000 square feet of available floor space — will be given to the Branch Laboratory. Great progress has been made on the building, and it is hoped that we shall be able to occupy it shortly after March first. The added space will go far toward rectifying the unfavorable conditions under which the work has been done for the past three years, and which have been mentioned above. It is hoped and expected that the new laboratory will be ideal in every way. It is planned to have a thoroughly modern cleaning and media room, a roomy and well arranged serological laboratory, sterile rooms for cultural work in the bacteriological laboratory, a chemical laboratory, an office and a library. Provision is also made for two rooms for research work. The expansion of the office will contribute much to the efficiency of the entire laboratory. The chemical laboratory will provide facilities for work which up to the present it has been impossible to carry on in the Branch Laboratory. The research rooms will offer an opportunity for the study of special problems, and the library especially will be of great assistance in training and maintaining an efficient and contented staff.

Water and Analytical Chemical Laboratories

LEONARD M. WACHTER

The limited amount of rainfall during the greater part of the year 1921 created acute difficulties for many of the public and private water supplies throughout the state. This condition was reflected at the laboratory in the increased number of water examinations made during the year at the request of health officers as well as for the Division of Sanitary Engineering, now the Division of Sanitation.

There still exists the necessity of more efficient purification of public water supplies in certain municipalities. Placing too great reliance on sterilization alone to safeguard public water supplies would seem to be a recent tendency in many instances, instead of using sterilization as a final safety factor. These conditions make it all the more necessary that the sterilization plants be efficient installations and efficiently operated at all times. The importance of water sterilization justifies the discussion of this subject even though it has been mentioned in previous reports of the laboratory and we wish again to state that the laboratory is able to cooperate with the Division of Sanitation and the health officers by more frequent examinations of water from supplies receiving such treatment and thus aid in efforts to maintain the highest efficiency of water sterilization processes.

Special Chemical Examinations

The analysts of the water laboratory were called upon to make a large number of analyses during the year in connection with the production of arsphenamine. The work included the assaying of the raw materials and the analyzing of the intermediates and the finished products. This work represented the largest part of the special chemical examinations that were made.

A number of trade wastes were examined for the Division of Sanitation in a cooperative study of the cause of tastes and odors in connection with the water supply of Waterloo.

Chemical examinations supplementing the bacteriological work done by the diagnostic laboratory were made in a study of a large number of cases of acute illness with rapid onset that occurred among the patrons of a factory restaurant at Binghamton.

A large number of toy balloons were examined in an effort to determine, if possible, the cause of the skin irritation that affected a number of school children at Fonda who had played with toy balloons after they were broken. The cause of the trouble was not definitely determined.

Equipment and Construction

The head of the water laboratory has devoted a large amount of time to assisting the Director with the development and installation of the larger apparatus and equipment in the laboratory and in the general supervision of laboratory employees in obtaining a semblance of order on the grounds by grading and by starting service roads around the building. Considerable supervision has also been needed in the completion of the interior of the stable units by laboratory workmen and in their equipment.

Luncheon Room

During the year two large, well-lighted and somewhat isolated rooms have been assigned to the luncheon room, thus making the service more satisfactory. As in previous years, luncheons have been served for thirty-five cents, and for those who bring their own lunches, supplementary dishes have been provided at nominal cost. This service has been rendered, and a small balance maintained, in spite of continued high costs, high labor turnover, and the fluctuation in attendance which has been caused by the absence of workers at meetings and on field investigations.

Executive and Secretarial Offices

I. M. DUTTON

The progress which the various secretarial units of the office have made toward better organization has been conspicuously aided by the lower labor turnover in the laboratory during the year. This was reduced from 61 per cent in 1920 to 28 per cent in 1921. Also, the office staff of the Branch Laboratory in New York City is in a more satisfactory condition this year than it has been at any time previously. With the installation of new equipment and the addition to the staff of a worker trained in the office of the main laboratory the development planned in 1920 is progressing encouragingly.

Our plans for future development were greatly stimulated by the thorough and keen but sympathetic investigation of our present standard procedures by the Board of Estimate and Control appointed by Governor Miller to review the operations of all the state departments. This investigation and the fact that members of the staff have been permitted to visit other laboratories and to attend scientific and commercial gatherings in the state where the best standard methods have been discussed and equipment displayed, have tended to make the office staff and its plan of organization of greater value not only to the workers within the laboratory but to those who have visited it or been interested in knowing how it operated in conjunction with the individual laboratories and the other divisions of the health department. Inquiries of various kinds from several of the United States have been answered as well as those from foreign countries — Czecho-Slovakia, India, Brazil. One hundred and seventy visitors from India, Canada, Serbia, Czecho-Slovakia, England, France, Philippine Islands, Norway, Switzerland, Japan, China, Brazil, and from sixteen of the United States have inspected the laboratory and several have spent a period varying from two weeks to eight or nine months in studying the standard procedures in detail. The Federal Board for Vocational Training has already assigned three ex-service people to this laboratory for training.

The growth of the work of the laboratory has made it necessary to use storage space for workrooms and the problem of storing reserve stocks of laboratory equipment and supplies in a satisfactory and convenient manner is each year becoming a greater one. We look to the approval of requests for new construction to relieve this condition.

Preparation and Sterilization of Glassware and Media

ELEANOR M. HUMPHREYS

The past year has been a period of adjustment and organization. Little new apparatus has been secured, and the equipment has been increased only by the building of necessary shelves and of a cabinet for the storage of materials. We have been occupied with the revision of procedures, with the aim of making the best use of the equipment at our disposal.

Sterilization

In January the old gas autoclaves were removed and the practice of having contaminated material collected and sterilized by a member of the night staff was discontinued. All work of sterilization is now performed during the day by members of the staff.

The two "American" sterilizers are now equipped with vapor-tension capillary thermometers, a type which is more satisfactory than mercury instruments for use when dry heat at high temperatures is employed for sterilization.

Glassware Preparation

The work of the glassware group has been very heavy. With the reduced staff we have had difficulty in taking care of the increased volume of work during the past months. However, by means of cooperation among all groups of the department, we have succeeded in meeting all demands.

During the year we have adopted the use of ½, 1 and 2 gallon green glass bottles, in place of the large flint glass bottles previously used to contain plasma, serum, etc. These are much less expensive than flint glass bottles and have proved very satisfactory.

We now have little difficulty in supplying satisfactory glassware to other departments. We met one problem this year in which it was necessary to employ a special grade of cotton in stoppering tubes. The ordinary grades were found to contain too much oil and a high grade absorbent cotton had to be used for this work.

Boxing of Diagnostic Outfits

The boxing group has suffered from the same handicap as the glassware group, since in the present organization the work of these two groups is largely performed by assistants who divide their time between glassware preparation and boxing work. This group has been especially busy during the fall, due to the unusually heavy demand for diphtheria outfits and culture tubes. In addition this group has been devoting all the time possible to the preparation of handbag outfits for distribution to physicians.

During the early part of the year the boxing group was able to spend some time salvaging dull and used needles. A considerable saving was effected.

As to volume of work, there has been a moderate increase in the total number of outfits assembled during 1921 over those prepared in 1920, and a decided increase in the number of diphtheria culture tubes without mailing cases. (In 1920, total outfits, 195,438; diphtheria culture tubes, 45,808. In 1921, total outfits, 233,574; diphtheria culture tubes, 76,790.) Among complete outfits, there has been a moderate or slight increase in the number of all outfits assembled excepting sputum outfits for the diagnosis of tuberculosis. In addition there was a marked decrease in the number of venereal disease blood outfits (without outer containers) prepared for use in state institutions.

Two new outfits have been added to the number of those assembled, in addition to the handbag outfit mentioned above. The first is an enteric disease blood outfit, to be employed as an alternative to the slides used in securing specimens for the Widal test. The other is a Keidel tube containing broth, to be employed in securing blood cultures. One point to be mentioned with regard to the assembling of handbag outfits is that each one completed involves the preparation of seven individual outfits.

Media Preparation

The media group has been especially busy during the fall months, keeping pace with the demand for Loeffler's medium for use in the diagnosis of diphtheria. An unusual quantity of this material has been prepared recently. We have experimented with various methods of heating, and have been fairly successful in producing a uniformly satisfactory material. However, we have one important problem to solve in connection with the preparation of this medium. We must find a method of keeping it from drying which will be more satisfactory than the process of sealing with paraffin which we now employ.

During the year we have revised our formulae for the preparation of media. In addition, wherever possible, we now adjust the reaction of media by the colorimetric method of determining the concentration of hydrogen ions. We have worked in conjunction with other departments on a study of methods and in consequence certain procedures have been revised. We have been able to produce much more satisfactory products, especially in the case of broth for testing sterility, of a modified Endo's medium for enteric disease work, and of a dextrose serum agar plating medium for use in testing the virulence of diphtheria-like organisms.

As far as total figures indicate, there has been a slight decrease in the volume of medium and solutions prepared during 1921. However, there is one fact which deserves emphasis. The decrease has been in the group of routine, heat-sterilized media, while there has been a marked increase in the amount of media combined with precautions to insure sterility.

Miscellaneous The work of the year has been accomplished with a decided decrease in staff. Since October first we have had one less worker in the sterilization group. The glassware boxing group has lost eight workers since July first, with three replacements. The permanent media group lost two workers, with one replacement. This makes a net decrease of seven workers in the permanent staff. The loss in the media group has been more than made up, however, by the assistance rendered by three federal students.

Fewer workers than usual have come to the department for brief periods of observation and training.

In conclusion, I wish to express my appreciation of the way in which the other departments have cooperated with us in our special problems. Further, I wish to commend the facilities of the library and scientific file and the excellent service rendered by the library staff.

Library

MARY WILLIAMS

If space permitted much might well be said in regard to the development of the library during the past year. With an adequate staff, sufficient resources as regards literature and all necessary equipment, the library affords free access to the more important literature upon the scientific subjects of interest and value to the laboratory, and supplies needed assistance in looking up references and in preparing manuscript for publication. The library is not only the center toward which all scientific workers turn for stimulus and information in connection with their work, but more and more the advantages it supplies are appreciated by the workers. It is gratifying to notice improvement in the reports and papers prepared by the members of the staff, which in turn indicate the amount of investigation and study going on in the laboratory, and to be able to report increased ability on the part of the library assistants to conserve time and effort in their work while rendering better service.

As the Director has emphasized in previous reports, his idea in regard to the establishment and development of a laboratory library is not merely to have a collection of books and journals, or even to limit the library activities to those usually included under the phrase " library work "; he wishes to consider the library as a point of concentration around which the research and investigation of the laboratory shall gather. Consequently, many related activities are included which are usually performed elsewhere, and the scope of the library work is continually expanding to keep pace with the continued development of the laboratory.

The unit or group is called the " library group " because library methods of classification, indexing and so forth are used in caring for the various kinds of material, such as books, pamphlets, lantern slides and museum material, and also for the arrangement and indexing of typewritten and manuscript reports and papers preserved in a permanent scientific file. This file which forms part of the library collection serves as the archives, as it were, of the laboratory activities.

As at present organized, the first duty of the librarian is to acquire, preserve and bring to the notice of workers literature bearing on laboratory activities, and to see that in arrangement and appearance the library room is really the center where scholarly reading and study are encouraged. On the other hand, it is the duty of certain members of the library group to help members of the staff to prepare the results of scientific work in the form of memoranda and reports which are suitable for preservation in the library or for publication. Also it is the duty of one person to notice, not merely if the material is handed in promptly, but to call attention if the reports themselves do not fulfill the purpose for which they are requested. They should not be long; should not require much time to write; but should be clear, concise and to the point, showing that even the junior workers are thinking about and studying their work.

The centralization of library activities, some of which might well be termed secretarial, has necessitated a larger library staff than would otherwise be necessary; yet when the character of the work is considered and it is realized that the different parts are dependent one upon the other, the arrangement is seen to be more economical and satisfactory than if two or more groups were organized separately. Many of the problems of the State Laboratory are also problems of the local laboratories or are of special interest to them, so that the laboratory library with its complete files of standard procedures, and full reports of special investigations and researches, reviews of literature and so forth, may serve not only the State Laboratory, but also other public health laboratories throughout the state.

The brief survey of the library activities made by the committee appointed by Governor Miller has stimulated the library group to continued study of their problems. During the past year the routine work has been under constant discussion and has become well systematized.

Although the library is primarily intended for the use of the scientific workers, particularly to increase interest in their work and to encourage them to study their problems, it is also intended to be of value to all the laboratory workers. Items of scientific interest, notices of meetings other than those connected with the laboratory are posted on the bulletin boards.

At present the library takes about seventy-five periodicals of interest and value to the laboratory staff, including representative foreign journals in bacteriology, pathology and experimental medicine. All these journals are necessary in such a large public health laboratory where a variety of subjects are under investigation, and where scientific workers should be informed of the latest results in bacteriology, chemistry and the other medical sciences as they are related to infection and immunity and to the field of public health. The current numbers of these journals, together with the bound volumes of back numbers and all other literature are kept easily accessible in the large library room. The books do not circulate. After some discussion it was decided to keep all literature in the library. As the room is always open and may be used at all times the regulation is reasonable and it works advantageously rather than otherwise in the interests of the research workers.

The degree of improvement in effective service made by the library during the past year, and the hopeful outlook of being able not only to stimulate intellectual activity among the laboratory staff, but to help foreshadow the direction in which some of such activity may be formulated, has been possible because the Director has insisted upon having, as far as possible, experienced persons for the work. The library group of the laboratory starts the coming year in better position than ever before to serve the needs of the scientific staff.

Abstracts of Reports From Local Laboratories

BUFFALO CITY LABORATORY

DR. THOMAS B. CARPENTER, *Superintendent of Laboratories*

(From Report to the City Health Officer)

The total number of examinations made has remained practically the same for the past three years (99,257 for 1921). A decrease in the incidence of diphtheria has resulted in a decrease of 25 per cent in the number of cultures examined, but there has been an increase of 21 per cent in the number of examinations for evidence of venereal diseases. "The figures show a healthy increase in the work performed, and all this under rather adverse circumstances."

"We have no clerical help, thus rendering it necessary to detail for this purpose technicians from the laboratory, and disinfectors. With the immense amount of detailed report work necessary to get out each day, it can be readily understood that difficulties must necessarily be encountered in utilizing untrained clerks for this work. I also beg to report that the State Department of Health, under whose approval we carry on our work, has severely criticized this lack of clerical help, and also criticizes the necessity for hurrying along the great amount of work done, with an insufficient personnel. It is due to the great industry and faithfulness of the laboratory workers that it has been possible to accomplish so much, under circumstances which should not exist."

CITY OF KINGSTON LABORATORY

B. ELEANOR EASTON, *Bacteriologist*

"The work has been the usual routine which has about equaled in volume that of 1920. It is interesting to note, however, that the public health work of the county has practically doubled during the past year. This is attributed to the establishment of a district laboratory supply station. Through the distribution of outfits we have become acquainted with the Health Officers of the county, many of whom have visited our laboratory, and with many of the other physicians. I believe the establishment of such supply stations to be a very effective means of bringing the physicians into closer touch with the local laboratory to the advantage of both the physician and laboratory worker."

ROCHESTER CITY LABORATORY

DR. G. W. GOLER, *Director*

Besides the routine public health examinations during the summer various soft drinks, wells at summer resorts and water on lake steamers were tested. About 50 per cent of these contained members of the colon group in either 1 cc. or 10 cc. quantities.

During the very hot weather counts were made on water from Lake Ontario taken at various points on the bathing beaches. These counts varied from 300 to 1,000,000 per cc., the average being about 2,000. The beaches were at no time considered unsafe for bathing.

SYRACUSE CITY LABORATORY

DR. A. G. GIGGER, *Bacteriologist*

Dr. Gigger's résumé is given in substance:

"During the recent epidemic of typhoid fever we had from various physicians a total of twenty-four blood cultures. Of this number sixteen were positive, four negative. Subsequent Widals on some also proved positive. It is interesting to note that while all were suspects only the sixteen which were positive developed typhoid fever.

"One interesting case in which a positive blood culture was obtained was that of Mrs. G. One son had typhoid fever and she took care of him. She was inoculated by her physician against typhoid and paratyphoid. In spite of this she developed the disease which ran a typical course with recovery. This case was one of several where typhoid fever developed before the inoculation had a chance to develop an immunity.

"In view of these facts it would seem that physicians should avail themselves of blood cultures as a routine in obscure conditions.

"Another source of gratification is the cooperation of the school nurses of the Department of Education in keeping watch of school children with sore throats, discharging noses, etc. They have conscientiously cultured these and many were positive. They have recultured also children returning to school from an attack of diphtheria.

"When children have been taken out of school on account of diphtheria, the nurses have cultured the other scholars in the room. This required considerable time as in some cases there were large classes in the room. Many times the nurses have sent in as many as eighty or one hundred cultures a day."

MADISON COUNTY LABORATORY

DR. R. L. CROCKETT, *Director*

"On November 1, 1921, the Madison County Laboratory was moved from the Devereux Block, Oneida, N. Y., to rooms at the Broad Street Hospital and the services of a technician secured to assist in the work. It is expected that, by this change, the work will be much facilitated and improved service will result.

"Owing to the prevalence of diphtheria in this section for the past two months the volume of work has increased considerably, over 500 throat cultures having been examined during November and December, 1921."

SARATOGA COUNTY LABORATORY

ADA L. BAILEY, *Bacteriologist*

This laboratory was installed in the Saratoga Hospital in August, 1920, by Miss Janet Bourn and was taken over by the county in April, 1921. Since Miss Bourn's resignation, July first, Miss Ada L. Bailey, formerly of the State Laboratory, has had charge of the work.

November first the city appropriated $500 to pay an assistant.

The variety of examinations made is steadily increasing, more physicians are using the laboratory and interest seems to be developing.

CRAIG COLONY LABORATORY

DR. W. T. SHANAHAN, *Medical Superintendent*

The résumé submitted by Dr. Shanahan seems especially interesting and is quoted:

"A considerable number of spinal fluids from selected patients has been carefully examined without finding any significant abnormality by ordinary methods.

"Haematological pictures in the endocrine glands have been carefully studied as the opportunity has presented itself. The results have been particularly consistent and striking in hypopituitarism. Briefly they may be summarized as follows: Frank and clear cut cases showed distinct eosinophilia approximating 20 per cent in some of the more exaggerated cases. Border line cases and cases receiving organotherapy showed unusually high and persistent mononucleaosis (pathological excess in the proportion of lymphocytes and endotheliocytes). All cases showed a polymorphonuclear leucocytosis which we are inclined to discount because of the fact that practically all cases had bad teeth. The most significant finding, we consider, is the mononucleosis which is helpful in the diagnosis of suspected border line cases which have a tendency to linger for an appreciable period after the inauguration of hormone therapy; while the eosinophilia, although interesting, is manifested most clearly only in those frank cases of pituitary dysfunction where lack of endocrine balance is quite distinctly suggested by other clinical symptoms.

"A moderate amount of biochemical research has been carried on during the year. It is disappointing to note that, so far at least, our analysis of the various constituents of the blood has provided only disappointingly negative data.

"It is intended to continue our blood chemical analysis and also to apply some of those delicate microchemical reactions to the future study of cerebrospinal fluids. Further an increase in the scope of our bacteriological work has been made possible by recent receipt of a much needed Arnold steam sterilizer.

"The cooperation of the Division of Laboratories and Research of the State Department of Health has been much appreciated and the plans formulated for the coming year anticipate a continuance of this pleasant and helpful relation."

UTICA STATE HOSPITAL LABORATORY

DR. C. L. RUSSELL, *Director*

The work of this laboratory consists largely of post-mortem examinations, fifty-one having been done during the past year.

Sections of the brain and of the endocrine glands were studied in all cases, and sections of such internal organs as showed pathological changes.

From these sections, 592 preparations were stained and studied for microscopical changes.

The number of clinical laboratory examinations has slowly but gradually increased, the total for the year being 793.

ST. MARK'S CLINICAL X-RAY LABORATORIES

DR. BYRON C. DARLING, *Director*

The laboratory service has shown steady growth since its establishment in March, 1920. During 1920 the average monthly increase in number of specimens was 41; in 1921, 118, while the increase for the year was 171 per cent (2,271 to 6,155). "In order to bring out the full value of the laboratory for the patient, a change was made early in January, 1921, from a fee basis for each examination to a graded lump sum laboratory fee for all routine work, with an individual fee for only such special examinations as blood chemistry, salvarsanized serum, vaccines, colloidal gold, etc." An increase in staff has also been made so that instead of three workers, only one of whom devoted full time, there are now four, three of whom give full time to the laboratory work.

"The development of a laboratory service which will prove attractive to physicians for their private work is expected to be one of the main points of growth during the coming year."

VON WEDEL LABORATORIES

DR. H. VON WEDEL, *Director*

There has been a marked increase in the volume of work, especially in the number of specimens for blood chemical tests. Dr. von Wedel is contemplating installing another laboratory in New Rochelle as the physicians realize more and more the value of laboratory work.

PAPERS PRESENTED DURING 1921

Standardization of laboratory work in New York State.. Augustus Wadwsorth, M. D.

Read before the Pathological Section of the Buffalo Academy of Medicine, January 26, 1921.

The scientific background of the modern hospital....... Augustus Wadsworth, M. D.

Read at the Annual Meeting of the Board of Directors and Staff of the Hahnemann Hospital in Rochester, N. Y., February 15, 1921.

Cooperation between the central State Laboratory and the local Municipal and County Laboratories....................... Augustus Wadsworth, M. D.

Read at the Annual Meeting of the Medical Society of the State of New York held in Brooklyn, N. Y., May 4, 1921.

Published in the New York State Journal of Medicine, 1921, 21, 386.

The action of bacterial culture products on phagocytosis.
Augustus Wadsworth, M. D., and E. N. Hoppe.

Read by Dr. Wadsworth at the Thirty-sixth Meeting of the Association of American Physicians held at Atlantic City, May 11, 1921.

Published in the Journal of Immunology, 1921, 6, 399.

The action of leucocytes and brain tissue on diphtheria and tetanus toxins.
Augustus Wadsworth, M. D., and R. Vories.

Published in the Journal of Immunology, 1921, 6, 413.

Public health work of state departments of health in relation to research.
Augustus Wadsworth, M. D.

Read at Conference of Division of States Relations of the National Research Council in Washington, D. C., May 27, 1921.

Cooperation between a central state laboratory and local municipal and county laboratories............................... Augustus Wadsworth, M. D.

Read before the Section on Preventive Medicine and Public Health of the American Medical Association in Boston, Mass., June 8, 1921.

Published in the Journal of the American Medical Association, 1921, 77, 512.

Discussion by Dr. Wadsworth of Dr. Paul A. Lewis' paper " Fundamental features of the complement deviation reaction as applied to tuberculosis" before the Pathological Section of the National Tuberculosis Association, New York City, June 15, 1921.

The importance of local laboratories.................. Augustus Wadsworth, M. D.

Read at the meeting of the Washington County Medical Society, Hudson Falls, N. Y., October 4, 1921.

Observations on the agglutinative and hemolytic action of calf serum on sheep's cells.
Frank Maltaner and Elizabeth Johnston.

Read at the Eighth Annual Meeting of the American Association of Immunologists at Cleveland, Ohio, March 24, 1921.

Published in the Journal of Immunology, 1921, 6, 271.

Observations upon the conglutination phenomenon.
Frank Maltaner and Elisabeth Johnston.

Read at the Eighth Annual Meeting of the American Association of Immunologists at Cleveland, Ohio, March 24-25, 1921.

Published in the Journal of Immunology, 921, 6, 349.

A comparative study of diagnoses made in various laboratories in New York State. Ruth Gilbert.

Read at the Annual Meeting of the Medical Society of the State of New York held in Brooklyn, N. Y., May 4, 1921.

A brief study of the influence of bacterial growth on the globulin content in spinal fluids.................................... Ruth Gilbert and Israel Cohan.

Read before the Laboratory Section of American Public Health Association in New York City, November 15, 1921.

The relative efficiency of various differential media for the isolation of organisms of the enteric disease group................ Ruth Gilbert and Marion B. Coleman.

Read before the Laboratory Section of the American Public Health Association in New York City, November 15, 1921.

The use of sterilized cultures for typhoid agglutination tests. Ruth Gilbert and Anna C. Moore.

Read before the Laboratory Section of the American Public Health Association in New York City, November 15, 1921.

A comparison of ice box fixation with water bath fixation for complement fixation tests with cholesterinised antigen................. H. Virginia Langworthy.

Read before the N. Y. State Association of Public Health Laboratories held at the State Laboratory, New Scotland Ave., October 13, 1921.

The use of a 15-minute titration period for the standardisation of the hemolytic system in the complement fixation test................... Anna C. Moore.

Read before the N. Y. State Association of Public Health Laboratories held at the State Laboratory, New Scotland Ave., October 13, 1921.

A comparison of the value of 0.6% and 6% salt solution in the glycerine outfits for submitting feces.................................... Marion B. Coleman.

Read before the N. Y. State Association of Public Health Laboratories held at the State Laboratory, New Scotland Ave., October 13, 1921.

Occasional irregularities in routine virulence tests.................. Helen H. Owen.

Read before the N. Y. State Association of Public Health Laboratories held at the State Laboratory, New Scotland Ave., October 13, 1921.

Lesions resembling tubercles noted in guinea pigs in which no acid-fast bacilli were found.. Israel Cohan.

Read before the N. Y. State Association of Public Health Laboratories held at the State Laboratory, New Scotland Ave., October 13, 1921.

* Poliomyelitis serum used in the treatment of poliomyelitis and the vaccine used against smallpox have been distributed only to meet special emergencies. Smallpox vaccine is not yet ready for general distribution. Supplies of the pure vaccine are sent to institutions or schools where it will be used immediately in order to secure practical tests of the variations in its potency, which cannot as yet apparently be controlled in the manufacture on a large scale. This vaccine is the pure vaccine prepared by the methods of Dr. Noguchi of the Rockefeller Institute.

SUMMARY OF DIAGNOSTIC EXAMINATIONS MADE BY THE APPROVED LABORATORIES OF NEW YORK STATE SINCE 1915

	1915	1916	1917	1918	1919	1920	1921
Division of Laboratories and Research, New York State Department of Health:							
Central Laboratory, Albany	48,430	74,621	82,693	69,396	121,288	162,416	185,308
Branch Laboratory, New York City	4,457	6,524	13,435	18,468	27,071	40,678	34,233
State Institute for Study of Malignant Disease, Buffalo	....	2,120	2,330	2,282	3,387	3,909	5,345
COUNTY LABORATORIES							
Amsterdam—Julius Wasserman Laboratory (Montgomery county)	....	....	1,482	1,472	3,278	1,878	7,720
Auburn—Cayuga County Laboratory; also municipal and private work	....	....	....	....	....	3,536	11,612
Batavia—Genesee County Laboratory; also municipal, hospital and private work	2,420	2,182	2,648	2,943	3,554	3,360	5,078
Belmont—Allegany County Hygienic Laboratory	107	488	583	643	618	1,383	1,664
Canandaigua—Ontario County Laboratory; also hospital work	1,507	1,379	1,408	934	1,544	823	1,887
Corning—Steuben County Hygienic Laboratory	4,268	5,617	7,536	7,055	9,147	8,521	10,324
Geneseo—Livingston County Laboratory	739	534	441	345	291	804	2,580
Glens Falls—Warren County Laboratory; also hospital and private work	3,520	6,263	5,205	1,875	4,326	4,910	6,908
Oneida—Madison County Bacteriological Laboratory; also hospital work	436	523	331	....	....	349	1,384
Pomona—Summit Park Sanatorium Laboratory; also municipal and private work	....	....	....	....	....	1,527	1,765
*Rochester—Monroe County Bacteriological Laboratory; also private work	....	....	....	....	....		2,776
*Saratoga Springs—Saratoga County Laboratory; also municipal, hospital and private work	....	....	....	....	....	....	2,307
MUNICIPAL LABORATORIES							
Buffalo—Bureau of Laboratories; also county work	33,336	35,606	47,923	49,115	98,222	100,714	101,651
Elmira—Elmira City Laboratory; also county, hospital and private work	3,931	4,520	4,683	3,658	2,639	3,007	3,968
Geneva—Geneva City Laboratory	....	....	....	....	....	8,089	7,892
Gloversville—Gloversville City Laboratory; also county, hospital and private work	277	421	967	1,606	415	427	1,934
Kingston—Kingston City Laboratory; also county work	....	....	....	....	1,651	3,834	5,313
Middletown—Laboratory of the City Health Department	....	....	....	36	303	458	581
Niagara Falls—Public Health Laboratory	794	3,297	7,367	....	....	9,628	18,750
Olean—Olean City Laboratory	....	....	1,080	....	676	1,906	2,091
*Poughkeepsie—Poughkeepsie City Laboratory	....	853	1,925	2,115	6,450	2,663	2,419
Rochester—Health Bureau Laboratory; also hospital work	2,545	3,596	7,053	7,727	11,296	19,099	24,695
Rome—Rome City Laboratory	258	631	522	569	220	995	2,232
Schenectady—Pathological Laboratory of the City and County of Schenectady; also hospital and private work	1,345	3,077	7,124	8,249	1,306	17,651	26,903
Syracuse—Laboratory of the Department of Health; also county work	11,623	15,853	16,918	13,215	14,907	17,820	29,535
Troy—Troy City Laboratory; also private work	1,372	1,388	1,766	2,487	4,000	3,851	4,556
Utica—Utica City Laboratory; also private work	643	765	....	2,506	5,594	5,446	6,588
Yonkers—Bureau of Health Laboratory	3,768	3,709	4,517	8,392	6,612	6,689	9,158

*** Approved at various times during 1921; figures represent work performed since approval.**

Hospital Laboratories							
Albany—Albany Hospital Laboratory; also county and private work	....	....	....	11,462	10,360	13,524	14,222
*Buffalo—Department of Laboratories, Buffalo General Hospital; also private work	....	....	....	....	....	5,259	5,254
**Buffalo—Division of Laboratories, Buffalo City Hospital and Dispensaries	....	....	....	....	....	....	....
*Cambridge—Laboratory of the Mary McClellan Hospital	....	....	....	....	....	....	3,203
Clifton Springs—Laboratory of the Clifton Springs Sanitarium; also municipal, county and private work	....	....	....	....	....	16,995	33,283
*Elmira—Arnot-Ogden Memorial Hospital	....	....	....	....	....	....	1,078
Newburgh—St. Luke's Hospital Pathological Laboratory; also private work	....	....	....	....	....	2,058	10,299
**Niagara Falls—Niagara Falls Memorial Hospital Laboratory; also private work	....	....	....	....	....	....	....
†Olean—Clinic Hospital Laboratory; also private work	....	....	....	....	....	....	5,434
*Port Jefferson—St. Charles' Hospital Laboratory; also municipal work	....	....	....	....	....	....	982
Poughkeepsie—Vassar Brothers Hospital Laboratory; also private work	....	....	....	....	....	5,186	7,418
Rochester—Highland Hospital Diagnostic and Research Laboratory	....	....	....	....	....	5,962	16,368
Rochester—Pathological Laboratory of Rochester Homeopathic Hospital; also private work	....	....	....	....	....	9,161	20,835
*†Troy—Cluett Pathological Laboratory, Samaritan Hospital	....	....	....	....	....	....	....
Trudeau—Trudeau Sanatorium Research and Clinical Laboratory	....	....	....	....	....	4,699	5,059
Utica—Clarke Memorial Laboratory, St. Elizabeth's Hospital; also private work	....	....	....	....	....	1,015	2,530
**Utica—Faxton Hospital Laboratory	....	....	....	....	....	....	....
**Valhalla—Grasslands Hospital; also county and private work	....	....	....	....	....	....	....
White Plains—Bloomingdale Hospital Laboratory; also private work	....	....	....	....	....	2,996	5,514
Yonkers—St. Joseph's Hospital Clinical Laboratory; also private work	....	....	....	....	....	996	1,970
State Institutions							
Binghamton—Binghamton State Hospital Laboratory	....	....	....	....	....	1,915	4,811
*Collins—Pathological Laboratory, Gowanda State Hospital; also municipal and private work	....	....	....	....	....	....	3,393
*Kings Park—Kings Park State Hospital Laboratory	....	....	....	....	....	....	5,498
*New York City—Manhattan State Hospital Laboratory	....	....	....	....	....	....	8,215
*New York City—New York State Psychiatric Institute	....	....	....	....	....	....	4,146
Ogdensburg—St. Lawrence State Hospital Laboratory	....	....	....	....	....	....	3,763
Poughkeepsie—Hudson River State Hospital Laboratory; also private work	....	....	....	1,806	2,120	4,729	6,823
**Rochester—Rochester State Hospital Laboratory	....	....	....	....	....	....	....
Sonyea—Craig Colony Laboratory	....	....	....	....	....	917	3,016
*Utica—George Alder Blumer Research Laboratory, Utica State Hospital	....	....	....	....	....	....	2,533
*Willard—Willard State Hospital	....	....	....	....	....	....	905
Educational Institutions							
*Ithaca—Laboratory of the New York State Veterinary College, Cornell University; also municipal work	....	....	....	....	....	....	780
Saranac Lake—Saranac Laboratory for the Study of Tuberculosis; also municipal and private work	....	....	....	....	....	3,962	5,145

---

* Approved at various times during 1921; figures represent work performed since approval.

** Approved during December 1921; therefore no reports were submitted.

† Complete reports of work for 1921 not filed.

SUMMARY OF DIAGNOSTIC EXAMINATIONS MADE BY THE APPROVED LABORATORIES OF NEW YORK STATE SINCE 1915 — *(Concluded)*

	1915	1916	1917	1918	1919	1920	1921
PRIVATE LABORATORIES							
Albany—Bender Hygienic Laboratory; also municipal and hospital work	9,836	12,398	14,583	5,557	17,483	22,620	23,274
Amsterdam—Laboratory of Dr. Lew H. Finch	....	....	....	....	....	5,233	8,880
Auburn—Laboratories of Chemical and Microscopical Diagnosis	....	....	....	....	....	569	....

SANITARY WATER EXAMINATIONS

	1909	1910	1911	1912	1913	1914	1915	1916	1917	1918	1919	1920	1921
Bacterial:													
Central laboratory, Albany	1,056	1,564	2,131	2,800	2,017	1,091	1,447	1,852	1,189	1,140	11	1,030	1,122
Branch laboratory, New York City												148	39
Chemical:													
Central laboratory, Albany	646	1,097	1,850	2,400	2,507	703	661	626	532	541	455	533	619

The decrease in the number of sanitary analyses since 1914 is due to the fact that careful field inspections on all samples of water sent to the laboratory for examination were then required for the first time.

ANALYTICAL RESULTS OF SAMPLES OF WATER OBTAINED FROM PUBLIC SUPPLIES OR SUPPLIES USED BY PUBLIC INSTITUTIONS

(Results in parts per Million)

CITY, TOWN OR VILLAGE	Source	Date	Color	Turbidity	NITROGEN AS — Free ammonia	Albuminoid ammonia	Nitrites	Nitrates	Chlorine as chlorides	Hardness, total	Alkalinity	Oxygen consumed	BACTERIA PER C. C. 37° C.	20° C.	B. COLI TYPE (+ = PRESENT) (— = ABSENT) 10 c.c.	1 c.c.	1-10 c.c.	1-100 c.c.

Report of Director 11

I. Sewerage and sewage disposal:

(a) Examination of plans and issuance of permits for sewerage and sewage disposal:

Avoca (School district No. 2, Town of Avoca) 17
Brockport (Atlantic and Pacific Products Corporation) 17
Butler (Town) (Shefford Cheese Co., Inc.) 17
Camillus (Taunton Junior High School) (see Onondaga)
Canandaigua 17
Chappaqua (see Newcastle)
Chaumont (see Lyme)
Cherry Valley (Borden's Farm Product Co.) 19
Clyde 20
Cobleskill 20
Conewango (Conewango Dairymen's Cooperative Assn.) 20
Conquest (Town) (Shefford Cheese Co., Inc.) 21
Copake (Town) (Bettman & Sugarman) 21
Cornwall (Town) (property of M. Harrowich) 21
Dansville 21
Easthampton (Town) (Fisheries Product Co.) 22
East Rochester 22
East Syracuse (Syracuse Rubber Co., Inc.) 22
Eastview (Westchester County Almshouse) (see Mt. Pleasant)
Eltingville (see New York City)
Florida (Town) (Adirondack Power and Light Corp.) 22
Garden City (2) (Garden City Company) 23
Geddes (Town) (Junior High School near Split Rock) (see Onondaga)
Glen Cove (2) 23
Greenburg (Town) (Community of Saint Mary) 24
Greenport (Town) (Holbrook Company) 24
Haverstraw (Town) (Letchworth Village, Thiells) 24
Hempstead (Town) (School district No. 11) 24
Herkimer (County Tuberculosis Hospital) (see Salisbury)
Huntington (Town) (Sewer District) 25
Kingston (Kingston Fertilizer Co.) 25
Larchmont 25
Livonia (Town) (2) (Brown & Bailey Condensed Milk Co.) 26
Lyme (Town) (Chaumont Cheese Factory) 27
Lynbrook (School district No. 20, Town of Hempstead) 27
Madrid (Town) (Madrid Creamery) 27
Mamaroneck 27
Mamaroneck (Town) (3) (Sewer district No. 1) 28
Marcy (Town) (Utica State Hospital, Marcy Division) 28
Massena 28
Middletown (Town) (Dairymen's League Cooperative Assn., Inc.) 29
Monticello 29
Mount Pleasant (Town) (Westchester Co. Almshouse at Eastview) 29
New Castle (Town) (Children's Aid Society of City of N. Y.) 29
New Hartford (Town) (Utica Country Day School, Inc.) 29
New Lebanon (Town) (School district No. 1) 30
New York City (N. Y. Assn. for Improving the Conditions of the Poor) 30
North Elba (Town) (Benson & Emerson Camps) 30
Oneonta (Town) (School district No. 6) 31
Onondaga (Town) (School district No. 5) 31

I. Sewerage and sewage disposal—*Continued:*

(a) Examination of plans and issuance of permits for sewerage and sewage disposal—(*Continued*):

PAGE
Owasco (Town) (Owasco Country Club) 31
Painted Post (2) 31
Phillipstown (Town) (Surprise Lake Camp) 32
Plattsburg (U. S. Military Reservation) 32
Pleasantville (School district No. 9, Town of Mt. Pleasant) 32
Rensselaer (2) 33
Ripley (Town) (Telling Belle Vernon N. Y. Co., Inc.) 33
Rochester (Town) (Dairymen's League Cooperative Assn., Inc.) 34
Rockville Centre (School district No. 21 of the Town of Hempstead). 34
Rome (Town) (State School for Mental Defectives) 34
Salamanca 34
Salisbury (Town) (Herkimer County Tuberculosis Hospital) 35
Savannah (Shefford Cheese Co.) 35
Schenectady 35
Scottsville 36
Shawangunk (Town) (School district No. 5) 36
Shortsville (Papec Machine Co.) 36
Skaneateles (Town) (Skaneateles Paper Co.) 36
Southold (Town) (School district No. 5) 37
Spring Valley 37
Syracuse (2) 37
Tarrytown 45
Tuckahoe 45
Turin (Town) (School district No. 9) 45
Utica State Hospital (see Marcy)
Villenova (Town) (Villenova Cheese Factory Co.) 46
Warsaw 46
Watertown 46
Westmoreland (Bartlett Milk Station) 46
Wilson 46
Woodridge 47
Yorktown (Town) (Mohegan Inn Corp.) 47

(b) General investigations relating to sewerage and sewage disposal:

Eastwood 48
Richfield Springs 51
Warsaw 54
List of other investigations 56

II. Protection of public water supplies:

(a) Enactment and enforcement of rules and regulations for the protection of public water supplies:

Beacon 59
Brocton 63
Canton 66
Newark 70
Nunda 73
(b) Inspections of violations of rules for the protection of public water supplies 77
(c) Reports of enforcement of water supply protection rules submitted under general order 78

(d) Investigation of public water supplies:

Afton 79
Alden (see Western N. Y. Water Co.)
Alexandria Bay 80
Alfred 80
Amagansett 82
Amsterdam (typhoid fever) 83
Amsterdam 88
Andes 89
Angelica 89
Angola 90

II. Protection of public water supplies—*Continued:*
(d) Investigation of public water supplies—*Continued:*

REPORT OF THE DIRECTOR

Hermann M. Biggs, M. D., *Commissioner of Health, Albany, N. Y.:*

Dear Sir.— I have the honor to submit herewith the annual report of the Division of Sanitation for 1921.

The year 1921 has been one of unusual activity and far reaching importance to this branch of the work of the department. By legislative amendments to the Public Health, Village and Town Laws, which went into effect July 1, the Division of Sanitary Engineering was changed to a Division of Sanitation and the function of passing upon plans for sewerage and sewage and waste disposal was transferred to the State Engineer. As the result of these changes the division was reorganized and its force reduced approximately 60 per cent. Some positions were transferred to the State Engineer and other positions were abolished.

The new law (chapter 510 of the Laws of 1921) provides in general that plans for sewerage and sewage disposal, formerly passed upon by this department under the provisions of the Public Health, Village and Town Laws, must now be submitted to and receive the approval of the State Engineer before any permit issued by the State Commissioner of Health for the discharge of sewage or industrial wastes into the waters of the State becomes effective. Under this law application for the issuance of a permit should be made to the State Commissioner of Health when the plans for sewerage and sewage disposal are submitted to the State Engineer, but in general a permit will not be issued by the Commissioner of Health until the plans are approved by the State Engineer.

Except as indicated above, the work performed by the new division is substantially the same as that of the old one and is as follows: (1) The supervision and control over the sanitary quality of public water supplies, including field investigations, analytical studies and reports; (2) the enactment and enforcement of rules and regulations for the protection of public water supplies from contamination; (3) examination and approval of plans and expenditures for county mosquito extermination commissions; (4) investigation of public nuisances; (5) the examination into conditions of nuisance affecting life and health under order from the Governor; (6) investigations and studies of stream pollution and operation of water purification and sewage disposal plants; (7) examination and reports of sanitary conditions, equipment and operation of milk pasteurizing plants; (8) special investigations of sanitary conditions of parks, camps, fair grounds and other public gathering places; (9) examination of the sanitary conditions of state institutions; (10) advice to municipalities, corporations and individuals upon sanitary matters such as water supply, garbage disposal, plumbing, ventilation, drainage and general sanitation; (11) furnishing data to the Surgeon-General of United States Public Health Service regarding sanitary quality of water supplies used by common carriers in interstate traffic; (12)preparation of permits for the discharge of sewage, sewage effluent and industrial wastes.

Some idea as to the volume of the work handled by the Divisions of Sanitary Engineering and Sanitation during 1921 may be gained from the following table which gives numerical summaries of the more important lines of work and for purposes of comparison the same data for the years 1919 and 1920:

	1919	1920	1921
Letters and other correspondence referred to Division.	2,666	3,020	3,344
Letters and reports sent out	4,323	4,444	5,356
Plans examined and permits issued	125	127	81
Investigation of public water supplies	154	193	205
Investigation of sanitary conditions of state institutions	14	30	24
Investigation of sewage disposal plants	17	16	21
Investigation relating to sewerage systems	10	13	15
Investigation of milk pasterurizing plants	403	166	190
Investigation of stream pollution and nuisances	47	68	46
Conferences held with local officials	328	357	269
Lectures and addresses by staff	6	7	9

It will be noted from the above table that notwithstanding a reduction of approximately 60 per cent in the force of the division on July 1, the volume of matters handled in 1921 was considerably greater than the year before. In fact, the number of matters referred to the Division of Sanitation and the number of letters and reports sent out during the last six months of 1921 was 20 per cent greater than for the corresponding six months of the year 1920. This was due partly to the increasing demand in the State for assistance and advice from the division on matters of sanitation and partly to the long continued drought last summer which tended to deplete many public water supplies and give rise to very many complaints against nuisances and cases of stream pollution.

In order to handle the very large amount of work since July 1 it has been necessary for every member of the Division of Sanitation to work at his maximum capacity and efficiency, to put in considerable overtime, to curtail and postpone vacations and in many instances to work Saturday afternoons and Sundays. Notwithstanding these efforts to meet the demands made upon the Division, it has been impossible to comply with all requests for inspections and assistance, and such requests have repeatedly been received when every available man was in the field on other work. This has, of course, resulted in considerable delay and loss of efficiency. In order to properly handle the work and relieve the heavy burden that has been thrown upon the division and enable it to resume such work as inspection of milk pasteurizing plants and state institutions it is imperative that additional men qualified to satisfactorily perform the highly specialized work required in the division be provided.

No branch of the work of the Division of Sanitation is of greater importance than the work of investigating and supervising the sanitary quality of public water supplies, considering the fact that about 8,500,000 people of the state are served by such supplies. This work which has constituted one of the major functions of the Division of Sanitary Engineering since it was established in 1906 has been given special attention by the new Division of Sanitation. All of the nearly 550 public water supplies in the state have now been investigated once and many of them a number of times. Since 1906 the number of public water supplies in the state has increased from about 400 to approximately 550 and the number of persons served by such supplies has increased from about 6,000,000 to nearly 8,500,000. In the same period the number of supplies receiving purification or treatment has increased from 50 to 130 and the number of persons supplied by filtered or chlorinated water has increased from 700,000 to about 7,000,000. During the past year water filtration plants have been installed and put in operation at Tonawanda, Middleport and Wellsville, while the cities of Buffalo and North Tonawanda have voted to install filtration plants. Chlorination plants or additional units for the treatment of water have been installed at Ithaca, Batavia, Jamaica, Larchmont, Little Falls, Ossining, Antwerp, Catskill, Marcy (State Hospital), Monticello, Youngstown, Fallsburg, Fleischmanns, Grand Gorge, Haverstraw, Johnstown, Ithaca (Cornell University), Port Jervis, Wellsville, Oyster Bay, Huntington, Medina, Woodhaven, Beacon, Hyde Park-on-Hudson and by New York City at Grant City, Rockville Centre, Baldwins and Valhalla.

In this connection it might be pointed out that owing to the lack of rain last summer which resulted in a general shortage of water and depletion of many of the smaller supplies, making it necessary to augment such supplies by pumping from polluted and questionable sources, an unusually large number of requests were received by the division for advice and assistance in improving and safeguarding the sanitary qualities of such supplies. Whenever this condition was called to our attention the emergency chlorine apparatus of the department was installed, water officials were instructed as to its use and the apparatus was left in operation until the municipality could secure one of its own. The demand for assistance of this kind became so great that it was necessary for us to secure an additional chlorine apparatus, but even the extra equipment was inadequate to meet the demand and it was necessary for us to install cruder but nevertheless effective emergency hypochlorite plants for the sterilization or disinfection of polluted auxiliary supplies in a number of cases. Although this work seriously overtaxed the reduced force of the Division of Sanitation we were able to meet most of the demands for assistance of this kind and there was not a single outbreak of typhoid in the State which could be attributed to a public water supply. The prompt action taken by the Division in safeguarding the quality of public water supplies was in all probability largely instrumental in bringing about this result.

The acute shortage of water supplies of many municipalities and the serious inconveniences and hazards attending such shortage should be a warning for them to provide without delay water supplies of adequate quantity and satisfactory sanitary quality. A dry season such as occurred last summer may be experienced at any time in the future and this, together with the usual increase in consumption should prompt the water boards and water companies to prepare for such emergencies in the future.

During the year seven sets of rules and regulations for the protection of public water supplies were enacted by the Commissioner under the provisions of article 5 of the Public Health Law. These rules were in each case prepared by the Division following detailed inspections of the watersheds to which they related.

Very many complaints regarding public nuisances and stream pollutions were received during the past year, due largely to the unusually low flows, and in many cases to the complete drying up of streams. Although most of these complaints were referred to the local boards of health for suitable action it was necesary for the division to investigate the more important cases.

A special investigation of a public nuisance of long standing and considerable importance created by the discharge of vapors and gases from large industrial plants at Edgewater, N. J., and affecting residents of the Riverside Drive section of New York City was practically completed during the past year. This investigation has covered a number of years and has involved extended scientific studies and observations in order to determine the responsibility of and extent to which each of the plants shared in the nuisances. Many hearings were held by the Commissioner at which the complainants and manufacturers involved were represented. As the result of these investigations and hearings all of the plants involved have either so modified the processes of operation or installed scrubbers or vapor and gas consuming devices as to almost entirely eliminate the objectionable conditions created by the operation of these plants in so far as New York City is concerned.

The investigation of the sanitary condition, equipment and operation of milk pasteurizing plants supplying municipalities outside of New York City is one of the newer and more important functions undertaken by the division and the great improvements in these plants resulting from recommendations of our reports on inspections of the plants have demonstrated the efficiency of this work. Owing, however, to the fact that the position of the inspector who handled this work was abolished on July 1 as the result of the reorganization of the division, it has been necessary to temporarily suspend these investigations until provisions are made by the legislature to provide funds to employ a man competent to carry on this work. Advice has, however, been given by correspondence to local authorities regarding the construction, equipment and operation of milk pasteurizing plants and plans for new plants have been passed upon by the Division. Local ordinances prohibiting the sale of milk other than pasteurized or Grade A have been enacted by a number of municipalities and the constitutionality of one such ordinance has been passed upon and upheld by a justice of the Supreme Court of the State. During the year 190 plants were investigated.

Owing to the depleted force of the division it has been necessary to temporarily suspend the investigation of the sanitary condition of state institutions. This work, will, however, be continued as soon as practicable.

The report on the sanitary condition of over 80 fair grounds visited by some 1,800,000 persons annually was completed during the year. This report comprises a general report setting forth the results of the investigations and making general recommendations for improvements, together with a detailed memoranda of the conditions found to exist at each fair, with recommendations as to the necessary improvements. These reports and memoranda were sent to the fair ground authorities and local boards of health with directions for carrying out the recommendations. From correspondence with the local authorities it appears that steps have been taken in nearly every case to carry out our recommendations as soon as practicable.

In connection with the certification by the Surgeon-General of the United States Public Health Service as to the sanitary quality of the water supplies used by common carriers in interstate traffic under interstate quarantine regulations, we have furnished him with copies of reports on inspections and results of analyses of water supplies at some 80 places. This data furnished by us is used by the Surgeon-General as a basis for certifying to the sanitary quality of water supplies used for drinking or culinary purposes by railroads and steamship lines in interstate traffic.

Although the new law transferred the more strictly engineering work of passing upon plans to the State Engineer, it properly left with the Commissioner of Health the issuance of permits and consequently the control over stream pollution and the safeguarding of sanitary quality of public water supplies. There are, however, certain inconsistencies in the law which should be corrected by the next legislature. There are, moreover, inconsistencies and deficiencies in the Public Health Law which seriously handicap the work of the Division and limit the effectiveness of its work, especially in improving the sanitary quality of public water supplies and controlling stream pollution. In order to correct these conditions it would be necessary to amend the Public Health Law and it is expected that bills will be introduced in the legislature which, if passed, would give the Department more effective control over these important matters.

Respectfully submitted

C. A. HOLMQUIST

December 31, 1921 *Director*

EXAMINATION OF PLANS AND ISSUANCE OF PERMITS

Sections 76, 77 and 78 of the Public Health Law prohibit in general the discharge of sewage, sewage effluent or any decomposable or putrescible wastes into any of the waters of the State unless express permission to do so shall have been first given in writing by the State Commissioner of Health, and provide that he may stipulate under what conditions such discharge may take place. Prior to July 1 of this year the Public Health, Village and Town Laws also provided that plans for sewerage, sewage and waste disposal should be submitted to and receive the approval of the State Commissioner of Health before the installation of such works. These laws, however, were amended by chapter 510 of the Laws of 1921 which became effective on July 1, 1921. The new law provides that plans for sewerage and sewage disposal must be approved by the State Engineer before any permit issued by the State Commissioner of Health for the discharge of sewage or wastes becomes effective.

Although this law resulted in transferring the work of passing upon plans to the State Engineer it left with the Commissioner of Health the matter of issuing permits and consequently the control over stream pollution. During the first half of this year 44 sets of plans for sewerage and sewage disposal were passed upon and permits issued by this Department. Since July 1 37 permits for the discharge of sewage and sewage effluent in connection with plans approved by the State Engineer were issued. Practically all permits issued contained the provisions that the sewerage or sewage disposal works shall be fully constructed in complete conformity with the approved plans; that no storm water or surface water from streets, roofs or other areas shall be admitted to the works; that no sludge or scum shall be discharged into any stream or other body of water or deposited on the ground where they may be washed thereinto by rain or melting snow; and that, whenever required, plans for additional or more complete treatment of the sewage or wastes shall be submitted.

In 1921 plans for sewers, sewer systems and sewage disposal works were approved and permits issued in the places listed below. Only the reports on examination of plans passed upon in connection with two of the more important cases are printed.

AVOCA (School District No. 2, Town of Avoca)

Plans for a sewage disposal plant, consisting of a settling tank and subsurface irrigation system, to serve the public school located in the village of Avoca, in School District No. 2 of the town of Avoca, were approved by the State Engineer on September 19, 1921, and a permit was issued to the board of education of this district by the State Commissioner of Health on September 21, 1921, to discharge effluent from this plant into the ground waters of the State tributary to Salmon creek under the usual conditions.

BROCKPORT (Atlantic and Pacific Products Corporation)

Plans for an industrial waste disposal plant, consisting of a fine mesh revolving screen, a three-unit settling tank, a sludge drying bed and a sand filter to serve the factory of the Atlantic and Pacific Products Corporation, comprising a milk condensery and tomato cannery, located at Brockport, Monroe county, were approved on April 26, 1921, and a permit was issued to this corporation on April 26, 1921, to discharge the effluent from the settling tank, comprising a portion of the disposal plant to treat the industrial wastes from this factory, into the waters of the stream tributary to Salmon creek within the village of Brockport, under the following provision in addition to the usual conditions:

> That whenever required by the State Commissioner of Health, the dosing tank and sand filters shown by the plans approved this day shall be constructed and placed in operation.

BUTLER (T) (Shefford Cheese Company)

Plans for a disposal plant for industrial wastes, consisting of a settling tank and sand filter, to serve the factory of the Shefford Cheese Company, Inc., located at South Butler, Wayne county, were approved by the State Engineer on November 14, 1921, and a permit was issued to the company by the State Commissioner of Health on November 21, 1921, to discharge effluent from the proposed plant of this factory of the company, into the waters of Butler creek, near the factory, within the town of Butler, under the usual conditions.

CANANDAIGUA

The plans for sewer extensions and a sewage treatment plant for the city of Canandaigua, Ontario county, N. Y., were submitted to this Department for approval by the board of public works on March 28, 1921.

Population and environment: The population in 1890 was 5,800; in 1900, 6,200; 1910, 7,200, and in 1920, 7,356. The engineer for the city estimates that its population 30 years from now will be about 10,000. The municipal water supply is taken from Lake Canandaigua.

Present system: The present sewer system, constructed about 30 years ago, embraces nearly all of the city with the exception of a certain portion of Main street and Green street, which are now provided for by the present plans application for the approval of which is included with the application for approval of the disposal plant. At present the sewage of the city is cared for by two trunk sewers, the smaller one, the western outlet sewer, is an 18-inch sewer, while the eastern outlet sewer, which collects the greater portion of the sewage from the city, is 24 inches in diameter.

Dilution available: Canandaigua outlet flows from the lake 25 miles in a northeasterly direction to a point of discharge in the Clyde river, whose waters reach Lake Ontario through the Seneca and Oswego rivers. The hamlets of Chapin, Shortsville, Manchester and Clifton Springs are located on the outlet and within 10 miles of Canandaigua. It was learned from the engineer that it is proposed to control the discharge from the feeder, into which the city sewers discharge, so as to facilitate sewage dilution. The feeder itself leaves the lake near the foot of Main street and enters the main outlet and discharges into Canandaigua outlet about 2 miles below. At ordinary times about the same amount of flow passes through each of these two lake outlets.

Plans submitted: The plans now submitted were submitted in compliance with a notification of this Department to the city council. These plans show that it is proposed to intercept the sewage from these two existing outfall sewers and carry it by gravity to a proposed disposal plant consisting of a screen chamber, pumping station, primary settling tanks of the two-story type, dosing chamber, sprinkling filter, final settling basin and auxiliary sludge drying beds. The plant is to be located midway between the two outlets, about 600 feet from the feeder. Here the sewage will be screened and then will be raised by pumps to pass through the two-story settling tank. The effluent from this tank will, when necessary, be further treated by sprinkling filters which are shown in detail, but permission is sought to discharge the effluent from the tanks directly into the stream, deferring filtration until later.

Sewer extensions: The sewer extensions along the east side of Main street and through Green street embrace about 1 mile of vitrified pipe. All of this is 12-inch with the exception of about 1,600 feet on the southern end of Main street, which is 8-inch. There are many houses situated along these sewer extensions which have hitherto been without sewerage provisions. All sewer extensions are shown provided with manholes at all points of intersection and nowhere farther apart than 400 feet, and are laid on slopes which are considered self-cleansing under ordinary conditions. The other extensions consist of two 18-inch intercepting sewers, one, about 2,500 feet long, to connect the west side sewer with the disposal plant, and the other, 1,100 feet long, to connect the east side sewer with the disposal plant.

Plant site: The site selected for the sewage treatment works appears to be reasonably remote from the developed sections of the city and is reported to be very much cheaper than any other available site on lower ground. The site is approximately centrally located with respect to the two main outlet sewers and appears to be 1,000 feet from the nearest house.

Screen chamber: The screen chamber is 10 feet long by 20 feet in plan and about 15 feet deep, built of concrete reinforced throughout. The screen is to be pitched 45 degrees and is to be composed of bars ½ inch by 2 inches, spaced on 2-inch centers. These bars are provided with lugs extending from the bottom and perforated for tiebolts. The platform for screenings is arranged with perforations so that material raked upon it will readily drain.

Pump house: The pump house is to be 20 feet by 20 feet in plan and about 20 feet deep and is to be built of reinforced concrete. Two half floors are provided, the one near the ground level being for storage of material and office use while the other half floor, protruding from the existing wall halfway between the ground floor and the pump level, supports the motors which are further supported by iron framing resting on the bottom. The pumps connected to the motors are each 1⅜ million gallons capacity centrifugal pumps and are provided with a branch suction pipe to the sump in the pump well, as well as with the main suction pipe. The pump capacity appears adequate to care for the flow of domestic sewage of the city provided ground water and surface water are excluded.

Settling tank: The settling tank is of the 2-story type, constructed in duplicate and provided with side gutters permiting a complete reversal of the direction of the flow. Overall dimensions of the tank in plan are approximately 70 feet long by 40 feet wide. The settling troughs are each 12 feet wide by 18 feet deep, with bottom sloping 1-1/5 on 1. Their combined capacity is about 175,000 gallons. Underneath each of the two settling troughs are 3 hoppers which, with space above them, have a combined capacity for sludge of about 15,000 cubic feet, measuring from one foot below the slot in the bottom of the settling trough. For the present population of 8,000 persons, and the engineer's estimate of maximum flow of about 125 gallons per capita, provision for sedimentation and sludge storage appear satisfactory.

Sludge removal: The sludge is to be discharged onto the sludge drying beds by means of 8-inch cast-iron pipes, terminating in 10-inch cast-iron pipes with 10-inch vitrified branches leading to each sludge bed. The sludge pipes terminate at a point 15 inches above the surface of the bed and have a slope of not less than 2 feet in 100.

Sludge beds: The plans provide for 2 sludge beds, each 50 feet by 100 in size, providing an area of 1¼ square feet per capita, which is liberal. They are composed of very coarse sand underlaid by 11 or more inches of gravel.

Dosing tank: The first of the units of the supplementary works to be constructed when required is the concrete dosing chamber. This chamber receives by gravity the flow from the 2-story settling tank and supplies intermittent doses to the sprinkling filters. This dosing tank has a maximum capacity of about 13,000 gallons and a minimum capacity of about 10,000 gallons. It is provided with a 24-inch automatic discharge siphon leading into a 30-inch main distributing pipe which carries the discharge from the dosing tank to the distribution system of the sprinkling filter.

Sprinkling filter: The sprinkling filter is 279 feet long by 114 feet wide and contains 250-⅞-inch Taylor nozzles, spaced about 11½ feet apart. The minimum depth of filter material is about 6 feet. The filter medium itself is broken stone 1½-inch to 3 inches in size. At the rate of 300,000 gallons per acre foot per day this filter would care for 1,800,000 gallons.

Secondary settling tank: The secondary settling tank has a capacity of 1,000,000 gallons. It is 140 feet long by 40 feet wide by 2 feet deep at the corners and 3 feet deep in the valley at the center. This valley is provided at one end with a 6-inch plugged cast-iron outlet for future pump connection and sludge removal. The overflow from the secondary tank passes over the weir and thence into a manhole where it joins the effluent from the settling tank and is carried to the river by means of a 20-inch vitrified pipe 150 feet in length.

Interceptor elevations: An examination of the plans unaccompanied by a contour map and complete elevations of the existing sewerage system, cannot be entirely conclusive as to certain economic features and it is recommended that further study be given to the possibility of lowering the elevation of the settling tank, even more than is suggested in the report of the consulting engineer and the adjustment of its intercepting sewer connections, so that the flow from the larger or both of the intercepting sewers can be conveyed to the settling tank by gravity and as much as possible of pumping be dispensed with until such time as it may be necessary to install sprinkling filters or further treatment.

A permit was granted to the board of public works of this city on April 6, 1921, to discharge effluent from the primary settling tank, comprising a portion of the proposed sewage disposal works into the waters of the feeder branch of the Canandaigua lake outlet under the following provision in addition to the usual conditions:

> That whenever required by the State Department of Health the dosing tank, sprinkling filter and final settling tank shown by the plans approved this day, shall be constructed and put in operation.

CHERRY VALLEY (Borden's Farm Products Company)

Plans for an industrial waste disposal plant consisting of a large settling tank subdivided into 2 chambers and an outlet sewer to serve the plant of the factory of the Borden's Farm Products Company, Inc., in the village of Cherry Valley, Otsego county, were approved by the State Engineer on July 18, 1921, and a permit was issued to the company by the State Commissioner of Health on July 26, 1921, to discharge the effluent from the proposed disposal plant to treat the waste water and washings from this factory of the company into the waters of Cherry Valley brook in the village of Cherry Valley, under the following provisions in addition to the usual conditions:

> That whenever required by the State Commissioner of Health, the outfall sewer shall be extended to a point below the confluence of Big Pond and Cherry Valley creeks or to such intermediate point as he may determine.
>
> That no whey, sanitary sewage or surface water from roofs or other areas shall be admitted to the proposed disposal plant.
>
> That whenever required by the State Commissioner of Health, detailed plans for the extension of the outfall sewer or for additional works designed to effect a more complete treatment of the waste water and washings shall be submitted to the State Engineer for approval; and that, upon the approval of said plans, such extensions, additions or supplementary works shall be constructed and placed in operation at such time or times thereafter as said Commissioner may designate.

CLYDE

On March 16, 1921, permission was given to the village of Clyde, Wayne county, to temporarily omit certain portions of the sewerage system and sewage disposal works shown on the plans approved by the State Commissioner of Health on April 14, 1920, as amended by plans approved by him on March 16, 1921.

COBLESKILL

Plans for sewer extensions on Elm street, Harder avenue, Washington street, Grove street and from the proposed interceptor extending along Cobleskill creek between Harder avenue and South Grand street in the village of Cobleskill, Schoharie county, were approved by the State Engineer on August 15, 1921, and a permit was issued to the board of sewer commissioners of the village by the State Commissioner of Health on August 18, 1921, to discharge sewage from the proposed sewer extensions into the waters of Cobleskill creek through the present outfall sewer discharging opposite the fair grounds within the village of Cobleskill, under the following provision in addition to the usual conditions:

> That on or before March 1, 1922, satisfactory detailed plans for works for the preliminary treatment of all the domestic sewage of the village of Cobleskill, accompanied by general plans for supplementary works for more complete treatment of the sewage, shall be submitted to the State Engineer for approval; and that, after the approval of said plans, any or all portions of such works for the preliminary treatment of the sewage of the village shall be constructed and put in operation at such time or times as the State Commissioner of Health may designate.

CONEWANGO (Conewango Dairymen's Cooperative Association)

A permit to discharge effluent from an industrial waste disposal plant consisting of a large settling tank and outfall sewer to serve the pasteurizing plant of the Conewango Dairymen's Cooperative Association at Conewango valley, in the town of Conewango, Cattaraugus county, into the waters of Conewango creek, within the town of Conewango was granted to this company on June 18, 1921, under the following provisions, in addition to the usual conditions:

That all of the waste water and washings shall be passed through a settling tank having a capacity of about 1 day's flow of wastes from the plant and so located and constructed that additional works for purification of the wastes may be installed and operated by gravity flow if possible.

That no sewage or other wastes containing human excreta or washings and no whey, skim milk, buttermilk or other wastes containing any considerable amounts of putrescible organic matter shall be discharged into the settling tank.

CONQUEST (T) (Shefford Cheese Company, Inc.)

Plans for an industrial waste disposal plant consisting of a large tank subdivided by baffles with an interior and an outlet sewer to serve the Spring Lake creamery of the Shefford Cheese Company, Inc., situated near the hamlet of Spring Lake, in the town of Conquest, Cayuga county, were approved on June 7, 1921, and a permit was issued to the Shefford Cheese Company, Inc., on that date to discharge the effluent from the proposed disposal plant to care for the waste water and washings from this creamery, into the waters of Duck Lake Outlet creek, within the town of Conquest, under the following provisions, in addition to the usual conditions:

That the traps at the ends of the settling tank be omitted, that the depth of the tank below its outlet be increased to 4 feet and that the tank effluent be conducted to a point of submerged discharge in the creek at least 5 feet from shore.

That no domestic sewage and no whey, skim milk, buttermilk or other wastes containing any considerable amount of organic matter shall be discharged into the disposal plant or into the creek or any other body of water.

COPAKE (T) (Bettman and Sugarman)

Plans for a sewage disposal plant consisting of six large leaching cesspools to serve Camp Barrington on Upper Rhoda lake in the town of Copake, Columbia county, were approved on June 7, 1921, and a permit was issued to Sanford S. Bettman and Arthur M. Sugarman on the same date to discharge effluent from this disposal plant and these cesspools at Camp Barrington, into the ground waters tributary to Upper Rhoda lake and outlet stream within the town of Copake, under the following provision in addition to the usual conditions:

That a tight iron pipe shall be used to make the connection from the old house to the new cesspool provided for that house.

CORNWALL (T) (Property of M. Harrowich)

Plans for a sewage disposal plant consisting of a leaching cesspool, a group of three cesspools and a new main plant embracing a settling tank and subsurface irrigation field to serve the property of Dr. Max Harrowich, located on Bay View avenue in the town of Cornwall, Orange county, were approved on May 16, 1921, and a permit was issued to Dr. Harrowich on the same date to discharge the effluent from this plant serving this property into the ground waters tributary to the Hudson river, within the town of Cornwall under the usual conditions.

DANSVILLE

Plans for sewer extensions to serve a district in the northern section of the village of Dansville, located os Morey avenue. Clinton and Elizabeth streets, Livingston boulevard and the Circle, in the village of Dansville, Livingston county, were approved by the State Engineer on November 3, 1921, and a permit was issued by the State Commissioner of Health to the sewer commissioners of the village of Dansville, and upon the receipt of an application on December 13, 1921, a permit was granted to the board of sewer commissioners on that date to discharge sewage from these proposed sewer extensions after treatment in the village sewage disposal plant, into the waters of Canaseraga creek through the existing outlet at a point about 635 feet west of the disposal works, within the town of North Dansville under the following provision in addition to the usual conditions:

> That on or before February 1, 1922, satisfactory detailed plans for modifications in the existing sewage disposal plant shall be submitted to the State Engineer for approval; and that within four months after the approval of such plans said modifications shall be carried out.

EASTHAMPTON (T) (Fisheries Products Co.)

Amended plans for a sewage disposal plant consisting of extensive treatment tanks, cinder screens and separating apparatus, to serve the fish factory of the Fisheries Products Company, near the hamlet of Promised Land in the town of East Hampton, Suffolk county, were approved on April 13, 1921. Since the discharge of no additional wastes beyond that contemplated by the permit issued on May 22, 1920, was planned, the issuance of a further permit in connection with this approval of these plans was not necessary.

EAST ROCHESTER

Amended plans for sewer extensions consisting of sewers on Drumore Crescent, Seven House lane, Upper Crescent, Winding Way and Woodneath Crescent streets and where shown on adjacent streets, to serve a subdivision in the vicinity of West McKinley street in the village of East Rochester, Monroe county, were approved on June 11, 1921, and a permit was issued to the board of trustees of this village to discharge sewage from these proposed extensions into the waters of Irondequoit creek after the sewage shall first have been passed through the village disposal plant, within the village of East Rochester under the usual conditions.

EAST SYRACUSE (Syracuse Rubber Company, Inc.)

A permit to discharge effluent from a sewage disposal plant comprising a settling tank and outlet sewer to treat the domestic or sanitary sewage from the factory of the Syracuse Rubber Company, Inc., located on Thompson road, in the village of East Syracuse, Onondaga county into the waters of Headson creek within the village of East Syracuse was granted on February 15, 1921, under the following provision in addition to the usual conditions:

> That no surface or storm water from roofs or other areas and no industrial wastes shall be discharged into or passed through the settling tank.

FLORIDA (T) (Adirondack Power and Light Corporation)

Plans for a sewage disposal plant consisting of a large tank with submerged outlet and outfall sewer to treat the domestic and sanitary sewage from the electric power plant of the Adirondack Power and Light Corporation in the town of Florida, Montgomery county, located at Lock No. 10, of the State Barge canal near the city of Amsterdam, were approved by the State Engineer on November 10, 1921, and a permit was issued to the corporation on November 21, 1921, by the State Commissioner of Health to discharge effluent from this disposal plant into the waters of the Mohawk river near Lock No. 10, within the town of Florida, under the usual conditions.

GARDEN CITY (Garden City Company)

Plans for an extension to a sewage pumping station comprising the addition of a new 300 gallon per minute motor driven pump and housing therefor to serve the Cedar Valley Pumping station of the Garden City Company located in the town of Hempstead near the village boundary of Garden City, were approved on February 18, 1921, on condition that a separately located emergency power line be installed to operate the electric motors of the pumping station or that power for the pumps be provided from an independent source. As the plans did not provide for the collection and discharge of additional sewage a permit was not issued in connection with these plans.

Amended plans for a sewage disposal plant consisting of enlargement to the screen chamber and settling tank and provisions for a large digestion tank, together with enlargement to the dosing chamber and sand filters; to serve the village of Garden City, Nassau county, were approved by the State Engineer on November 30, 1921, and a permit was issued on December 7, 1921, by the State Commissioner of Health, to discharge effluent from the sewage disposal plant as modified and extended into the ground waters tributary to Broad channel within the village of Garden City under the following provision in addition to the usual conditions:

> That the surface of the settling tanks shall be kept as free as practicable from scum and that the sludge shall never be allowed to accumulate to a depth of more than 8 feet in any part of the settling tank, or for such a period as to allow active fermentation to take place in the settling tank.

GLEN COVE

Plans for a sewer outlet and pumping station to serve the city of Glen Cove, Nassau county, were approved by the State Engineer on October 14, 1921, and a permit was issued to the city council on November 2, 1921, by the State Commissioner of Health to discharge effluent from the sewage disposal plant of the city, as modified and extended by the construction of this sewer outfall and pumping station, into the waters of Hempstead Harbor, opposite the foot of Garvies Point road, within the city of Glen Cove, under the following provisions in addition to the usual conditions:

> That before the proposed pumping station and outfall are put into operation, plans for a suitable sludge drying bed, or for some other satisfactory method of disposal of the sludge shall be submitted to and receive the approval of the State Engineer.
>
> That if the flow from the city sewers tributary to this disposal plant cannot be so reduced, or if this flow at any time becomes such, that the average detention period in the upper or sedimentation compartment of the settling tank is less than 2 hours or the minimum detention period less than 1 hour, one or more additional tanks shall be constructed so as to obtain at least these detention periods.
>
> That during the bathing season and the period when shell fish are taken from Hempstead Harbor and whenever required by the State Commissioner of Health, chlorine shall be uniformly applied to the effluent from the sewage disposal plant at the rate of not less than 10 parts per million by weight.

Plans for the proposed sewer extensions and sewage pumping stations to serve the city of Glen Cove, Nassau county, were approved by the State Engineer on November 3, 1921, and a permit was issued to the City Council on November 14, 1921 by the State Commissioner of Health to discharge sewage from the sewer extensions and sewage pumping stations shown on the approved plans, through the city sewage disposal plant on Glen Cove creek into the waters of Hempstead Harbor, opposite the foot of Garvies Point road within the city of Glen Cove, under the following provisions in addition to the usual conditions:

> That, on or before May 1, 1923, satisfactory plans showing in detail the existing pumping stations on Stanco street, Crescent Beach road, and Sea Cliff avenue, such modifications as may be necessary to provide greater capacity and duplicate pumping equipment for the Sea Cliff avenue station, and some satisfactory means of pumping the sewage from all the stations in case of failure of power or pumping machinery, shall be submitted to the State Engineer for approval.
>
> That, within three months after the approval of such plans, the modifications be made and satisfactory means of pumping the sewage from the stations in case of failure of the machinery or electrical power shall be provided.
>
> That, on or before December 30, 1922, accurate plans showing all the existing sewers in the city of Glen Cove shall be filed with the State Engineer and the State Commissioner of Health.

GREENBURG (T) (Community of St. Mary)

Plans for a sewage disposal plant consisting of a covered settling tank, contact bed and subsurface irrigation system to serve the proposed House of Mercy near Valhalla, in the town of Greenburg, Westchester county, were approved on February 28, 1921, and a permit was issued on the same day to the president of the Community of St. Mary of Peekskill, to discharge effluent from the proposed disposal works of the proposed House of Mercy into the waters tributary to the Bronx river within the town of Greenburg, under the usual conditions.

GREENPORT (T) (Holbrook Company)

Plans for a sewage disposal plant, consisting of a settling tank, pumping station and intermittent sand filters, to serve the automobile body factory of the Holbrook Company, located near the city of Hudson, town of Greenburg, Columbia county, were approved on March 16, 1921, and a permit was issued to the Holbrook Company on that date to discharge the effluent from the proposed treatment plant for this factory into the waters of Claverack creek, in the town of Greenburg under the following provision in addition to the usual conditions:

> That in the settling tank the inlet baffle shall terminate 3 feet above the bottom, and that two outlet pipes near the end of the partition be substituted for the single outlet shown at the center of the partition.

HAVERSTRAW (T) (Letchworth Village)

Plans for a sewage disposal plant, amended in accordance with the recommendations of this Department and embracing extensions to the sand filters and the addition of a chlorination building and apparatus to serve Letchworth Village, a state custodial asylum for mental defectives, located near the hamlet of Thiells, in the town of Haverstraw in Rockland county, were approved on January 6, 1921.

HEMPSTEAD (T) (School District No. 11)

Plans for a sewage disposal plant consisting of three separate units, each comprising a settling tank, and four leaching cesspools to serve the school on Terrell avenue, Oceanside, in School District No. 11 of the town of Hempstead, Nassau county, were approved by the State Engineer on October 27, 1921 and a permit was issued to the board of education of this school district by the State Commissioner of Health on November 2, 1921, to discharge effluent from this disposal plant into the ground waters tributary to East Rockaway creek, within the town of Hempstead, under the following provision in addition to the usual conditions:

> That whenever the sludge or scum shall accumulate so as to occupy more than ¼ of the depth of the settling tanks the sludge and scum shall be removed from the proposed tanks and disposed of by burying at such a place and in such a manner as not to create a nuisance.

HUNTINGTON (T) (Sewer District)

Plans for sewer extensions to be built in Long Swamp road, formerly Lenox avenue, in the town of Huntington, Suffolk county, were approved by the State Engineer on September 29, 1921, and a permit was issued to the sewer commissioners of the sewer district of the town of Huntington, by the State Commissioner of Health, on October 3, 1921, to discharge sewage from the proposed sewer extensions through the district disposal works into the waters of Huntington harbor, through the existing effluent outlet near the intersection of New York avenue and Mill Dam road, within the town of Huntington, under the usual conditions.

KINGSTON (Kingston Fertilizer Co.)

Plans for an industrial waste disposal plant, consisting of a settling tank and filter bed, to serve the rendering plant of Mr. Lewis E. Fischang, known as the plant of the Kingston Fertilizer Company, located on Chapel street, city of Kingston, Ulster county, were approved on May 7, 1921, and a permit was issued to Lewis E. Fischang on the same date to discharge the effluent from the proposed treatment plant into the waters of a tributary to Rondout creek, within the city of Kingston, under the following provision, in addition to the usual conditions:

> That the top 9-inch layer of gravel be omitted from the filter and that the underdrain be placed on the bottom of the filter bed, and have its upper end carried up to a guarded flushing vent 9 inches or more above the top of the bed.

LARCHMONT

Plans for sewer extensions on Addison street and Larchmont avenue, in Sewer District No. 1 of the village of Larchmont, Westchester county, were approved by the State Engineer on November 22, 1921, and a permit was issued by the State Commissioner of Health to the board of trustees of the village on December 7, 1921, to discharge sewage from the proposed sewer extensions, into the waters of Larchmont harbor and Long Island Sound through the existing Bonnet avenue outlet sewer opposite Cedar island, within the village of Larchmont, under the following provisions, in addition to the usual conditions:

> That after January 1, 1923, sewage from the proposed sewers shall not be discharged into Larchmont harbor on Long Island Sound without treatment, but shall be conveyed to and treated in the sewage disposal works to be constructed to treat the sewage from Sewer District No. 1 in the village of Larchmont, in accordance with notice to the board of trustees of the village of Larchmont, dated December 7, 1921.
>
> That, whenever required by the State Commissioner of Health, the sewage disposal plants for the treatment of the sewage from the other sewer districts of the village shall be constructed in accordance with the plans approved by this Department on March 2, 1917, and in accord-

ance with the provisions of a permit issued on the same date in connection with the approval of the plans or in accordance with plans subsequently approved and permits subsequently issued.

On December 7, 1921, the following notice was served on the board of trustees of the village:

To the Board of Trustees of the Village of Larchmont:

Pursuant to the provisions of the Public Health Law and in accordance with the conditions of the permits for the discharge of sewage from sewers in Chatsworth and Larchmont avenues and other streets into the waters of Larchmont harbor on Long Island sound at Larchmont, granted on June 13, 1911, and subsequent thereto, the village of Larchmont is hereby notified to construct all portions of the sewage disposal works at Bonnet avenue and the intercepting and outlet sewers connected therewith, shown by the plans approved on March 2, 1917, and April 8, 1918, or approved amendments thereto, and to have said works and sewers completed and put in operation by January 1, 1923.

This notice is given in accordance with and under the provisions of section 77 of chapter 45 of the Consolidated Laws (the Public Health Law), on the 7th day of December, 1921.

M. NICOLL, JR.
Deputy State Commissioner of Health

LIVONIA (T) (Brown and Bailey Condensed Milk Company)

A permit to discharge waste water and washings from an outfall sewer to serve the milk plant of the Brown and Bailey Condensed Milk Company, located at Lakeville, in the town of Livonia, Livingston county, into the waters of Conesus creek at or below the highway bridge on the Geneseo and Canandaigua highway, within the town of Livonia, was granted to this company on March 16, 1921, under the following conditions:

> That no untreated domestic sewage from closets or toilet rooms and no skimmed milk, whey, buttermilk or other wastes containing any considerable amount of organic matter shall be discharged into Conesus creek or any other body of water through the proposed outlet sewer.
>
> That whenever required by the State Commissioner of Health, satisfactory detailed plans for the treatment of the waste water and washings from the condensery of this company at Lakeville shall be submitted for approval; and upon the approval of such plans any or all portions of such treatment works shall be constructed and put in operation at such time or times thereafter as said Commissioner may designate.

On the same date a permit to discharge effluent from a sewage disposal plant consisting of a large settling tank for domestic sewage from the factory toilets, to serve this milk plant, into the waters of Conesus creek at the same point, was granted to this company under the following conditions:

> That the settling tank shall have a capacity equal to one day's flow of sewage from the condensery and that it shall be so located and constructed that additional works for more complete treatment of the sewage may be installed and operated by gravity flow if possible.
>
> That the effluent pipe from the settling tank shall be discharged into Conesus creek at a point at or below the highway bridge on the Geneseo to Canandaigua highway and that the outlet of the effluent pipe shall be extended out to a point near the middle of Conesus creek, where it will be submerged at all stages of flow in the creek.
>
> That no industrial wastes and no storm water, unpolluted condenser water and no skimmed milk, buttermilk or whey containing any considerable amount of organic matter shall be discharged into the settling tank.

LYME (T) (E. W. Coon Cheese Factory)

Plans for an industrial waste disposal plant consisting of a large settling tank, automatic dosing tank and three intermittent sand filters and an outfall laid in a rock crevice to serve the cheese factory of E. W. Coon in the town of Lyme, near the village of Chaumont, Jefferson county, were approved on April 25, 1921, and a permit was issued on the same date to E. W. Coon to discharge the effluent from the proposed disposal plant to treat the waste water and washings from this factory into the ground waters tributary to Saw Mill bay, within the town of Lyme, under the following provisions in addition to the usual conditions:

> That an 8-inch siphon discharging into 10-inch pipes leading to the filter beds be provided in place of the 6-inch siphon and 6-inch pipes shown and that the siphon be placed in a sump 5 inches deep.
>
> That the upper 2 feet of all filters shall be composed of clean sand of an effective size of between .2 m. m. and .45 m. m.; that the lower foot of the filtering material shall be of graded gravel; and that the underdrains shall be placed not more than 12 feet apart.
>
> That no sewage or other wastes containing human excreta or washings and no whey, skim milk, buttermilk or other wastes containing any considerable amounts of putrescible organic matter shall be discharged into the disposal plant.
>
> That whenever required by the State Commissioner of Health, the filter effluent shall be conducted to a submerged diffusion outlet in the bed of Horse creek channel or to deep water in Saw Mill bay.

LYNBROOK (School District No. 20, Town of Hempstead)

Plans for a disposal plant, consisting of two sewage disposal systems, each consisting of a septic tank overflowing into three leaching cesspools, to serve the Lynbrook High School of School District No. 20 of the town of Hempstead, located in the village of Lynbrook, Nassau county, were approved on June 7, 1921, and a permit was issued on the same date to the board of education of this district to discharge effluent from this proposed sewage treatment plant into the waters of East Rockaway creek, within the town of Hempstead, under the usual conditions.

MADRID (Madrid Creamery)

Plans for an industrial waste disposal, consisting of a settling tank, subsurface absorption field and leaching cesspools, to serve the Madrid Creamery, located on North street, in the village of Madrid, St. Lawrence county, were approved on April 1, 1921, and a permit was issued on the same date to Mr. W. J. Agen to discharge the effluent from the proposed disposal plant, to treat the waste water and washings from this creamery into the ground waters tributary to the Grass river, within the town of Madrid, under the following provision, in addition to the usual conditions:

> That no domestic sewage or other wastes containing human excreta, and no whey, skim milk, buttermilk or other wastes, containing any considerable amounts of putrescible organic matter, shall be discharged into the proposed disposal plant.

MAMARONECK

Preliminary plans for a sewage disposal plant, contemplating the construction of a sewage disposal works, consisting of a pumping station, fine screen and an activated sludge plant, to be located on the southwest corner of Harbor island, to serve the village of Mamaroneck, Westchester county, were approved by the State Engineer on October 25, 1921. A permit was issued by the State Commissioner of Health to the board of trustees of the village of Mamaroneck on October 28, 1921, to discharge effluent from the proposed sewage disposal works shown by these plans, into the waters of Mamaroneck harbor, within the village of Mamaroneck, under the following provision, in addition to the usual conditions:

> That satisfactory detailed plans for the disposal works, the connecting trunk sewers and all appurtenances connected therewith, shall be submitted to and receive the approval of the State Engineer before the construction of the proposed disposal works, connecting trunk sewers and appurtenances is commenced.

MAMARONECK (T) (Sewer District No. 1)

Original plans for a sewer system for District No. 1 of the town of Mamaroneck, Westchester county, were approved on July 15, 1920. These plans provided for a separate sewer system covering 356 acres, having a present population of 600 and an estimated future population of 7,000, and for the treatment of the sewage from this system in works to be constructed and operated jointly with the village of Larchmont. This arrangement did not prove feasible, and on March 17, 1921, plans for modifications of the sewer system and for an independent disposal plant for the sewer district were approved. On June 11, 1921, amended plans were approved, which provided for a change of location of the disposal plant to be built in connection with the sewerage system, and on July 13, 1921, amended plans, providing for so adjusting the sewerage system as to permit to connecting it with the disposal plant at the new location, were approved by the State Engineer. In addition to the usual conditions, the permit issued on March 21, 1921, for the sewer system provided as follows:

> That before the pumping station and force main for subdistrict B, or I-A. M. L. are constructed, detailed plans for said pumping station and force main shall be submitted to and receive the approval of this Department.
>
> That before any of the sewers not shown in detail by the approval plans are constructed, satisfactory detailed plans of said sewers shall be submitted to and receive the approval of this Department.

MARCY (T) (Utica State Hospital, Marcy Division)

Amended plans for a change in the outlet pipe below the chlorination building to the sewage disposal plant serving the Marcy Division of the Utica State Hospital, in the town of Marcy, Oneida county, were approved on January 3, 1921, together with a profile showing the proposed change.

MASSENA

Plans for sewer extensions consisting of sewers on South Main street and Cook street in the village of Massena, St. Lawrence county, were approved on May 26, 1921, and a permit was issued on that date to the board of trustees of the village to discharge the sewage from the proposed extensions into the waters of the Raquette river at South Main street within the village of Massena under the following provision in addition to the usual conditions:

> That whenever required by the State Commissioner of Health, satisfactory detailed plans for works for the partial or preliminary treatment of the entire sewage of the village of Massena, shall be submitted for approval; and upon the approval of said plans any or all portions of such works for treatment of sewage shall be constructed and put in operation at such time or times thereafter as said Commissioner may designate.

MIDDLETOWN (T) (Dairymen's League Co-Operative Association, Inc.)

A permit to discharge effluent from a waste disposal plant consisting of a settling tank and an outfall sewer, to care for the waste water and washings from the Arkville condensery of the Dairymen's League Co-operative Association, Inc., located at the Hamlet of Arkville in the town of Middletown, Delaware county, into the waters of the east branch of the Delaware river within the town of Middletown was granted to the Association, on January 26, 1921, under the following provision in addition to the usual conditions:

> That all the waste water and washings shall be passed through a settling tank having a capacity of not less than the daily flow of waste from the condensery and so located and constructed that additional works for purification may be installed and operated by gravity flow, if possible.

MONTICELLO

Plans for a proposed sand filter to be constructed in connection with the existing sewage disposal plant of the village of Monticello, Sullivan county, were approved by the State Engineer on August 6, 1921, and a permit was issued on August 10, 1921, by the State Commissioner of Health to the board of sewer commissioners of the village to discharge effluent from the proposed sand filter into the waters of Cold Spring brook through the outlet of the existing sewage disposal plant within the village of Monticello, under the usual conditions.

MOUNT PLEASANT (T) (Westchester County Almshouse)

Plans for extensions to the sewage disposal plant consisting of settling tanks and sand filters, to serve the Westchester county almshouse at the hamlet of East View in the town of Mount Pleasant, Westchester county, were approved on April 6, 1921, and a permit was issued to the board of supervisors of the county of Westchester on the same date, to discharge effluent from this disposal plant into the waters of the Sawmill river within the town of Mount Pleasant under the usual conditions.

NEW CASTLE (T) (Children's Aid Society of the City of New York)

Amended plans for a sewage disposal plant embracing the addition of a sludge drying bed to serve the Convalescent Home of the Children's Aid Society of New York City, located near Chappaqua, town of New Castle, Westchester county, were approved by the State Engineer on September 29, 1921, and a permit was issued by the State Commissioner of Health to the Society on October 3, 1921, to discharge effluent from the proposed sludge drying bed into the waters of a tributary to Sawmill river through the effluent trench outlet of their existing sewage disposal plant within the town of New Castle under the usual conditions.

NEW HARTFORD (T) (Utica Country Day School)

Plans for a sewage disposal plant consisting of a large two-compartment settling tank and outfall sewer to serve the Utica Country Day School, Inc., located in the town of New Hartford, Oneida county, were approved by the State Engineer on August 9, 1921, and a permit was issued by the State Commissioner of Health on August 12, 1921, to this school to discharge effluent from the proposed sewage disposal plant into the waters of a tributary of Saquoit creek at the point of discharge shown on the plans within the town of New Hartford under the usual conditions.

NEW LEBANON (T) (School District No. 1)

Plans for a sewage disposal plant consisting of a settling tank and two fields of subsurface irrigation tile to serve the Union Free School in District No. 1 of the town of New Lebanon, Columbia county, located about 7 miles west of Pittsfield on the highway between Pittsfield and Albany, were approved on March 5, 1921, and a permit was issued on the same date to the board of education of this district to discharge effluent from this disposal plant into the ground waters tributary to Wyomanock creek within the town of New Lebanon under the following provisions, in addition to the usual conditions:

> That the submerged down-turned pipe on the inlet of the settling tank shall be omitted; that a transverse baffle, extending 2 feet below the flow line, shall be placed across the end of the tank, 1 foot from the inlet; and that a suitable vent with its top carried above the high water level shall be provided for the tank.
>
> That the manhole of the settling tank shall be carried up level with the surface of the ground and that this manhole shall be provided with a tight locked manhole cover.
>
> That watertight covers be provided for all openings into sewer and disposal systems which are lower than the highest ground or surface water level, and that these covers be maintained over these openings except while the openings are being properly used for examination and cleaning.
>
> That the subsurface tile drains shall be so laid that their inverts shall be in all cases at depths between 1 foot and 2 feet below the ground surface.

NEW YORK CITY (The New York Association for Improving the Condition of the Poor)

Plans for a sewer system and for a sewage disposal plant, comprising a subdivided settling tank and a chlorination apparatus for disinfecting the tank effluent, to serve the Summer Home of the New York Association for Improving the Condition of the Poor, located near the postoffice of Eltingville on Staten Island, in the borough of Richmond, New York city, were approved on May 6, 1921, and a permit issued to the Association on that date permitting the discharge of effluent of this plant into the waters of Lower New York bay at the point shown by the plans in the borough of Richmond, under the following provision in addition to the usual conditions:

> That chlorine gas shall be applied uniformly to the effluent from the settling tanks in the proportion of not less than 15 parts of the gas to 1,000,000 parts of effluent before it is discharged into Lower New York bay, and that this proportion shall be increased when required by the State Commissioner of Health.

NORTH ELBA (T) (Benson and Emerson Camps)

Plans of a sewage disposal plant, consisting of settling tanks and intermittent sand filters and effluent ditches to serve four houses and outbuildings on the Benson and Emerson estates on Buck island in Lake Placid, in the town of North Elba, Essex county, were approved on March 31, 1921, and a permit was issued to William S. Benson on the same date to discharge the effluent from the ditches of the proposed disposal plant to serve his camp and three other adjoining camps on Buck island into the ground waters tributary to Lake Placid within the town of North Elba, under the usual conditions.

ONEONTA (T) (School District No. 6)

Plans for a sewage disposal plant, consisting of a large cesspool overflowing into a series of leaching cesspools to serve the public school in District No. 6 of the town of Oneonta, Otsego county, located on the State Highway about one-half mile west of the Oneonta city line, were approved on April 13, 1921, and a permit was issued to the board of education on the same date to discharge effluent from these cesspools into the waters tributary to Otego creek or the Susquehanna river within the town of Oneonta, under the following provision, in addition to the usual conditions:

> That the cesspools shall be constructed with dry walls of masonry or hollow tile, open bottoms and depths not less than 5 feet below the flow line, and that a third cesspool at least 6 feet in diameter shall be built at once in addition to the two cesspools shown.

ONONDAGA (T) (School District No. 5)

Plans for a sewage disposal plant, consisting of a settling tank, dosing chamber and subsurface irrigation system, to serve the Taunton Junior High School, near Split Rock, in the town of Onondaga, in School District No. 5, in the towns of Onondaga, Geddes and Camillus, were approved by the State Engineer on December 16, 1921, and a permit was issued by the State Commissioner of Health to the board of education of this district on December 20, 1921, to discharge effluent from this plant into the ground waters tributary to Harbor brook on the property of said school, within the town of Onondaga, under the usual conditions.

OWASCO (T) (Owasco Country Club)

Plans for a sewage disposal plant, consisting of a large settling tank provided with a dosing chamber discharging into a subsurface system, to care for the camp and club house of the Owasco Country Club, located near the east side of Owasco lake in the town of Owasco, Cayuga county, were approved on April 22, 1921, and a permit was issued on the same date to the board of governors of the club to discharge effluent from the proposed disposal plant into the ground waters tributary to Owasco lake within the town of Owasco, under the usual conditions.

PAINTED POST

General plans for a sewer system, showing the location of the disposal plant, to consist of settling tanks and pumping plant to serve the village of Painted Post, Steuben county, were approved by the State Engineer on August 25, 1921, and a permit was issued to the board of trustees of the village by the State Commissioner of Health on the same date to discharge the effluent from the proposed sewage disposal plant into the waters of the Chemung river within this village, under the following provision, in addition to the usual conditions:

> That, prior to the commencement of the construction work on any sewers or sewerage structures shown by the present plans, satisfactory detailed plans for the Imhoff tanks and pumping plant, accompanied by general plans for additional or supplementary works for more complete treatment of the sewage, shall be submitted to, and receive the approval of, the State Engineer.

Plans for a sewage disposal plant, consisting of a coarse screen and settling tank, sludge drying bed and a pumping plant with additional units planned for later construction to serve the village of Painted Post, were approved by the State Engineer on December 1, 1921, and a permit was issued by the State Commissioner of Health on December 13, 1921, to the board of trustees of the village to discharge effluent from the proposed disposal plant shown in detail on these approved plans, into the waters of the Chemung river in this village, under the following provisions in addition to the usual conditions:

> That the proposed sewage disposal plant shown by the plans approved by the State Engineer on December 1, 1921, shall be fully constructed in complete conformity with such plans, except that one of the two settling tanks and one of the two sludge beds may be temporarily omitted from construction.
>
> That, whenever the average daily flow of sewage tributary to the proposed sewage disposal plant shall exceed 220,000 gallons, the settling tank and sludge bed shown by dotted lines on drawing No. 14 of the plans approved by the State Engineer on December 1, 1921, shall be constructed and put into operation.

PHILLIPSTOWN (T) (Surprise Lake Camp)

Plans for a sewage disposal plant, consisting of settling tanks, intermittent sand filters and effluent trenches, to serve the Surprise Lake Camp of the Educational Alliance and Young Men's Hebrew Association, town of Phillipstown, Putnam county, were approved by the State Engineer on October 8, 1921, and a permit was issued by the State Commissioner of Health on October 11, 1921, to the association to discharge effluent from this proposed plant into the waters of Breakneck brook on the property of the Association, within the town of Phillipstown, under the usual conditions.

PLATTSBURG (United States Military Reservation)

Plans for a 6-inch sewer to serve the latrine and bath house on the Reservation in the city of Plattsburg, Clinton county, were approved by the State Engineer on August 12, 1921, and a permit was issued by the State Commissioner of Health on August 18, 1921, to the commanding officer of the Reservation to discharge the sewage from the proposed sewer into the waters of Lake Champlain, opposite the property of the Reservation, within the city of Plattsburg, under the following provisions in addition to the usual conditions:

> That, whenever required by the State Commissioner of Health, satisfactory detailed plans for works for either the extension or relocation of said sewer, or both, shall be submitted to the State Engineer and Surveyor for approval; and that, upon the approval of said detailed plans, any or all portions of such works shall be constructed and put in operation at such time or times thereafter as the State Commissioner of Health may designate.
>
> That, whenever required by the State Commissioner of Health, satisfactory plans for a system of intercepting sewers and sewage disposal works for the collection and treatment of the entire sewage of the Reservation shall be submitted to the State Engineer and Surveyor for approval.

PLEASANTVILLE (School District No. 9)

Plans for a sewage disposal plant, consisting of a settling tank and three large leaching cesspools, to serve the Union Free School District No. 9 of the town of Mount Pleasant, located at Pleasantville, Westchester county, were approved by the State Engineer on December 7, 1921, and a permit was issued by the State Commissioner of Health to the board of education of this district on December 10, 1921, to discharge effluent from this sewage disposal plant into the ground waters of the State tributary to the Saw Mill river within the village of Pleasantville under the following provision, in addition to the usual conditions:

> That, whenever the seating capacity of the school is increased to 160, satisfactory detailed plans showing such modifications and enlargements of the plant as may be necessary shall be submitted to the State Engineer for approval; and, upon approval of said plans, any or all portions of such modifications and enlargements shall be constructed and put in operation at such time or times thereafter as the State Commissioner of Health may designate.

RENSSELAER

Plans for a sewer extension on Willow street in the city of Rensselaer, Rensselaer county, were approved on April 19, 1921, and a permit was issued to the common council of the city on the same date to discharge sewage from this proposed extension into the waters of the Hudson river through the existing outlet at the lower end of Herrick street, within the city of Rensselaer, under the condition that the sewer extension shown by plans approved this day shall be fully constructed in complete conformity with such plans or approved amendments thereof.

Plans for sewer extensions on Second street in the city of Rensselaer, Rensselaer county, were approved by the State Engineer on August 24, 1921, and a permit was issued by the State Commissioner of Health on August 30, 1921, to the common council of the city to discharge sewage from the proposed sewer extensions on Second street between Church street and Fowler avenue into the waters of the Hudson river, through the existing outlet at the lower end of Fowler avenue, within the city of Rensselaer, under the following provisions in addition to the usual conditions:

> That, whenever required by the State Commissioner of Health, satisfactory detailed plans for intercepting and outfall sewers to convey all the domestic sewage of the city to a suitable site for sewage disposal works, together with detailed plans for the preliminary treatment of all the domestic sewage of the city, and showing a suitable location and general plans for supplementary works for more complete treatment of domestic sewage, shall be submitted to the State Engineer and Surveyor for approval.
>
> That, upon approval of said plans, the intercepting and outfall sewers and works for the preliminary treatment of sewage, any or all portions of such sewers and works shall be constructed and put into operation at such time or times thereafter as said Commissioner may designate.

RIPLEY (T) (Telling Belle-Vernon, New York Co., Inc.)

A permit to discharge waste water and washings from an outlet sewer extending to Lake Erie, to serve the condensery of the Telling Belle–Vernon New York Company, Inc., located at Ripley, Chautauqua county, into the waters of Lake Erie, was granted to this company on April 5, 1921, under the following provisions in addition to the usual conditions:

> That no sewage or other wastes containing human excreta or washings, and no whey, skim milk, buttermilk or other wastes containing any considerable amounts of putrescible organic matter, shall be discharged into the lake with the waste water and washings.
>
> That, whenever required by the State Commissioner of Health, satisfactory detailed plans for treatment works, to treat the waste water and

> washings from the condensery before their discharge into Lake Erie, shall be submitted to this Department for approval; and that upon the approval of said plans such works for the treatment of the waste water and washings shall be constructed and put in operation at such time or times thereafter as said Commissioner may designate.

ROCHESTER (T) (Dairymen's League Cooperative Assn., Inc.)

A permit to discharge the effluent from a settling tank to serve the creamery of the Dairymen's League Cooperative Association, Inc., located in the town of Rochester, Ulster county, into the waters of Rondout creek was granted to this company on February 14, 1921, under the following provisions, in addition to the usual conditions:

> That all waste water and washings from this creamery shall be passed through a settling tank having a capacity of not less than the daily flow of wastes from the creamery, and so located and constructed that additional works for treatment of the wastes may be installed and operated by gravity flow, if possible.
>
> That, whenever required by the State Commissioner of Health, all whey or other wastes containing any considerable amounts of putrescible organic matter shall be excluded from the settling tank and disposed of in some other satisfactory manner.

ROCKVILLE CENTER (School District No. 21 of the Town of Hempstead)

Plans for a sewage disposal plant consisting of a settling tank and subsurface irrigation system to serve the Riverside public school of School District No. 21 of the town of Hempstead, located at Rockville Center, Nassau county, were approved by the State Engineer on December 19, 1921, and a permit was issued to the Board of Education on December 20, 1921, to discharge effluent from this sewage disposal plant into the ground waters on the school property within the village of Rockville Center under the following provision in addition to the usual conditions:

> That when sludge and scum accumulates so as to occupy one-fourth of the depth of the settling tanks, and not less than once a year, the sludge and scum shall be so removed and so disposed of by burying in some remote place as not to create a nuisance.

ROME (T) (State School for Mental Defectives)

Plans for the rehabilitation of a sewage disposal plant consisting of settling tanks, sludge drying beds, sprinkling filters and subsidence basins, to serve the State School for Mental Defectives, located in the town of Rome, in Oneida county, near the city of Rome, including modifications made in accordance with recommendations of this Department, were approved by the State Commissioner of Health on June 23, 1921.

SALAMANCA

Plans for sewer extensions on Broad and on Center streets and on Trout avenue in the city of Salamanca, Cattaraugus county, were approved by the State Engineer on November 19, 1921, and a permit was issued by the State Commissioner of Health on November 23, 1921, to the common council of the city to discharge sewage from the proposed sewer extensions into the waters of the Allegany river near the foot of Center street under the following provision in addition to the usual conditions:

That whenever required by the State Commissioner of Health, satisfactory detailed plans for intercepting outfall sewers to convey the entire sanitary sewage of the city to a suitable site for sewage disposal works, together with detailed plans for preliminary treatment works to treat the entire sanitary sewage of the city shall be submitted to the State Engineer for approval; and upon the approval of said plans any or all portions of such intercepting and outfall sewers and for such preliminary treatment works shall be constructed and put in operation at such time or times thereafter as said Commissioner may designate.

SALISBURY (T) (Herkimer County Tuberculosis Hospital)

Amended plans for a proposed new sewage disposal plant consisting of subdivided settling tank, dosing chamber, subsurface irrigation fields, sludge drying bed and drainage trench to serve the Herkimer County Tuberculosis Hospital, located in the town of Salisbury, Herkimer county, were approved by the State Engineer on August 31, 1921, and a permit was issued by the State Commissioner of Health on September 2, 1921, to the board of managers of this hospital to discharge effluent from this proposed sewage disposal plant into the ground waters tributary to Canada creek within the town of Salisbury, under the usual conditions.

SAVANNAH (The Shefford Cheese Company)

Plans for an industrial waste disposal plant consisting of settling tanks and a sand filter bed to serve the cheese factory of the Shefford Cheese Company, located at the village of Savannah, Wayne county, were approved by the State Engineer on October 27, 1921, and a permit was issued by the State Commissioner of Health on November 10, 1921, to the company to discharge the effluent from the proposed plant into the waters of a tributary to Crusoe creek within the village of Savannah, under the following provisions in addition to the usual conditions:

That when necessary the sludge or scum from the proposed plant shall be removed and disposed of in such a manner as to cause no nuisance, and the sludge and scum shall not be allowed to accumulate to a greater combined depth than one foot in any section of the sedimentation tank.

That no storm water or surface water and no whey, skim milk or other wastes containing any considerable amount of putrescible organic matter shall be discharged into the disposal plant.

That whenever the volume of wastes to be treated exceeds 1,000 gallons per day or whenever required by the State Commissioner of Health, satisfactory detailed plans for additional or other works for the treatment of the wastes shall be submitted to the State Engineer for approval; and upon approval of said plans, any or all portions of such works shall be constructed and put in operation at such time or times thereafter as said Commissioner may designate.

SCHENECTADY

Plans for proposed additions to the sewerage system of the eleventh ward of the city of Schenectady were approved by the State Engineer on December 23, 1921, and a permit was issued by the State Commissioner of Health on December 24, 1921, to the department of public works of the city to discharge sewage from the proposed sewers in the eleventh ward into the waters of the Mohawk river through the outlet of the city sewage disposal works within the town of Niskayuna, under the following provision in addition to the usual conditions:

That before January 1, 1923, a thorough study of the entire problem of sewerage and sewage disposal shall be made by a competent expert or experts and that there shall be submitted to the State Engineer and State Commissioner of Health satisfactory comprehensive plans for sewerage and sewage disposal works for the entire city involving necessary modifications of the existing systems of sewerage and sewage disposal works.

SCOTTSVILLE

Plans for a sewerage system and for a sewage disposal plant consisting of preliminary settling tanks, a pump well and outfall sewer to serve the village of Scottsville, Monroe county, were approved by the State Engineer on November 19, 1921, and a permit was issued by the State Commissioner of Health on November 23, 1921, to the board of trustees of the village to discharge effluent from this disposal plant to be constructed in connection with this proposed sewer system, into the waters of Allen creek at the site of the proposed disposal plant, within the town of Wheaton, under the usual conditions.

SHAWANGUNK (T) (School District No. 5)

Plans for an outfall sewer from the John G. Borden High School to the existing sewer below Second street at the Hamlet of Wallkill in the town of Shawangunk, Ulster county, were approved by the State Engineer on December 5, 1921, and a permit was issued by the State Commissioner of Health on December 7, 1921, to the board of education of School District No. 5 of the town of Shawangunk to discharge sewage from this school through the existing sewer below Second street into the waters tributary to the Wallkill river at a point of discharge shown by the approved plans, within the town of Shawangunk, under the following provision, in addition to the usual conditions:

> That on or before January 1, 1923, satisfactory detailed plans for works to treat the sewage of the John G. Borden High School and of the buildings connected or to be connected with the sewer shown by the plans approved on December 5, 1921, shall be submitted to the State Engineer for approval; and that after the approval of said plans, such work shall be constructed and put into operation on or before September 1, 1923.

SHORTSVILLE (Papec Machine Company)

Plans for a sewage disposal plant, comprising a two-story settling tank for the main buildings and two single compartment settling tanks for outlying dwellings, to serve the factory and housing group of the Papec Machine Company located at Shortsville, in the town of Manchester, Ontario county, were approved on June 11, 1921, and a permit was issued on that date to this company, to discharge effluent from this plant into the waters of Canandaigua outlet within the village of Shortsville, under the following provisions in addition to the usual conditions:

> That the length of the single compartment tank No. 2 near the millrace and Race street be increased from 12 feet to 16 feet.
>
> That the cleanout drains from the bottoms of these 2 single compartment tanks be either entirely omitted or terminated at some point where their discharge cannot overflow onto the ground or reach the waters of the millrace or the Canandaigua outlet.

SKANEATELES (T) (Skaneateles Paper Company)

Plans for a sewage disposal plant consisting of settling tanks and outlet sewers to treat the sewage from the Skaneateles Paper Mills and office buildings of the Skaneateles Paper Company in the hamlet of Willow Glen in the town of Skaneateles, Onondaga county, were approved on April 6, 1921, and a permit was issued on April 8, 1921, to the company to discharge effluent from the proposed plant into the waters of Skaneateles outlet within the town of Skaneateles, under the usual conditions.

SOUTHOLD (School District No. 5)

Plans for a sewage disposal plant consisting of a settling tank overflowing successively into 2 large leaching cesspools to serve the Union Free School in District No. 5 of the town of Southold, Suffolk county, were approved on June 7, 1921, and a permit was issued on that date to the board of trustees of this dictrict to discharge effluent from the proposed plant into the ground waters tributary to Southold bay within the town of Southold under the usual conditions.

SPRING VALLEY

Plans for a sewer system, consisting of 13 miles of sewers with 2 pumping stations, and a disposal plant, comprising a screen and grit chamber, double 2-story settling tanks, a chlorination tank and auxiliary sludge beds; to serve the village of Spring Valley, Rockland county were approved on February 17, 1921. On the same date a permit was granted to the board of trustees of the village to discharge effluent from this plant into the waters of Pascack creek within the town of Clarkstown under the following provisions in addition to the usual conditions:

> That the 400 feet of exposed iron sewer pipe along the pond between Lawrence street and the Pearl river be provided with proper cover or means of adjusting itself to temperature changes.
>
> That the screens in the screen chamber be set at an angle of between 30 and 45 degrees from the horizontal and provided with a perforated platform upon which screenings may be conveniently raked to drain.
>
> That the surface of the ground beneath the sludge filters be laid out in valleys in which to place the underdrains; that these drains be laid on a slope of not less than 1 per cent; that no point in the filter bed, including that over the underdrains, be less than 13 inches thick and that a suitable concrete apron or other means be provided to enable the sludge to spread over the bed without unduly disturbing its surface.
>
> That the chlorinating apparatus be installed in duplicate and that spare parts be provided and kept on hand.
>
> That chlorine gas shall be applied uniformly to the effluent from the settling tanks in the proportion of not less than 12 parts of the gas to 1 million parts of effluent before it is discharged into Pascack creek.

SYRACUSE

Plans for sewage disposal works to treat the sewage of the city of Syracuse, Onondaga county, N. Y., were submitted to this Department for approval by the Syracuse intercepting sewer board on December 30, 1920. An application for the approval of the plans signed by the members of the board under date of June 23, 1920, was also received.

Previous Records

Main Outfall Sewer: The records of this Department show that, on September 2, 1920, plans previously reported upon were approved for the final extension of the intercepting sewer to the site of the proposed plant on conditions, among others, that on or before January 1, 1921, satisfactory detailed plans for sewage disposal works and outfall sewers should be submitted to this Department for approval and that after the approval thereof said works and outfall sewers should be constructed and put in operation at such time as the State Commissioner of Health may designate.

Preliminary Approval of Works: On October 25, 1920, a preliminary approval was given to general plans for sewage treatment works submitted on June 25, 1920, with amendments submitted under dates of September 1, 1920, and October 23, 1920. It was stated in the letter giving the preliminary approval that the Department would probably not approve of a storm relief sewer discharging nearer the shore line than 700 feet; that if a single source of power were to be selected it be of a character which would insure continuous pumping operation; that this approval was founded primarily upon the general plans, conclusions and recommendations set forth in the report of the consulting engineers to the intercepting sewer board dated June 1, 1920; and that the approval applied only to such features shown upon the plans as relate to the arrangement and design of the sewage disposal works, pumping station and outfall pipes.

Population: For over 30 years the population of Syracuse has shown the exceptionally uniform and rapid rate of average annual increase of about 2¼ per cent reaching 171,717 in 1920. Though there are gas works and numerous factories, they are located near the water front or are of such a nature that so far as intercepted sewage contribution is concerned, the city may be said in general to be residential.

Water Supply and Sewerage: A gravity supply of about 26 million gallons a day is furnished to about 165,000 of the inhabitants and about the same number are tributary to the main intercepting sewer and proposed treatment plant. This interceptor provides sewerage facilities for all the territory of the city except about a square mile of outlying undeveloped farm land, tributary to Onondaga lake through Butternut creek. Another square mile of the city is sewered into the interceptor on the separate plan. Throughout all the rest of the city the sewage and storm water are combined and cared for by a system of combined sewers whose discharge into the brooks which traverse the city caused a nuisance there and in the Canal Harbor works.

Intercepting Sewers

Intercepting System: To remedy these insanitary conditions, a system of sewers, designed to intercept the maximum dry weather flow of domestic sewage and a certain amount of storm water from the combined sewers of the city, has been constructed. Plans have recently been approved as noted above for an extension of the main collector, or interceptor into which these intercepting sewers discharge. This main interceptor is 90 inches in diameter and has a fall of 9 feet in 10,000 below Hiawatha avenue which would give it a gravity discharge capacity of over 155,000,000 gallons a day when its discharge is not retarded by high water in the lake and provided the coefficient of hydraulic friction used in design be attained in construction. This flow mentioned is equal to twice the estimated maximum dry weather flow from an ultimate population of 400,000 persons in the tributary district of the city. Since the original and branch sewers were designed for rainfalls of from ½ to ¾ inches per hour and the interceptor capacity is equal to only about 1/45th of an inch runoff from the area served, it is obvious that, at times of considerable storms, most of the storm flow and the then commingled domestic sewage will for these short periods flow into the creeks, but even then, at separated intervals and under more favorable conditions for dispersion and dilution than before the construction of the intercepting system.

Basis of Design: The interceptor was designed for an assured dry weather flow of 125 gallons per capita, ½ running off in 8 hours, accompanied by an equal amount of storm water and this appears to be the maximum flow for which the interceptor may be called upon to care.

The following figures abstracted from the engineers' report, cover estimated population and quantity of sewage on which the design of the disposal plant is based:

Estimates of Population and Quantity of Sewage

SYRACUSE	1920	1930	1940	1950	1960
Total population	*171,647	207,000	243,000	282,000	325,000
Tributary population to works	158,000	190,000	220,000	250,000	280,000
Per cent population tributary	92	92	91	89	86
Average rate sewage flow at works, m.g.d.†	30.37	33.21	35.27	37.2	39
Gallons per capita daily §	191	175	160	149	139
Average rate for which works should be designed, m.g.d.‡	22.62	25.46	27.52	30.2	33.6
Gallons per capita daily§	143	134	125	121	120
Average rate of all sewage reaching Onondaga L. m.g.d	31.77	34.91	37.57	40	43
Gallons per capita daily	185	169	155	142	132

* Preliminary census report.

† Average dry weather sewage flow (less than average flow to be treated).

‡ Much of the storm flow included in these quantities will be diverted around the sewage treatment plant and discharged directly into Onondaga lake.

§ Based on tributary population.

Proposed Treatment

Present Plans: The present plans provide for the treatment of the sewage collected by the main interceptor in dry weather and the small portion of the polluted storm flow, in a plant located on the lake front near the junction of Lawroy street and Hiawatha avenue and to discharge from the plant through multiple outlets about ¼ mile from the shore and to discharge the excess flow in times of storm at the adjacent shore line. The sludge is to be buried in disinfecting chemical wastes. In detail: The sewage, from the outlet of a Venturi flume, at the end of the main interceptor, passes through a chamber where at times of heavy storms, which fill the sewer, the portions of storm discharge greater than 55 million gallons a day will flow through large sluice gates or over a long emergency weir and discharge at the margin or shore line of the lake, while the dry weather flow or combined flow at the rate of 55 million gallons a day will pass through a gate into a grit and screen chamber and thence into the pump house. Here it is to be lifted to flow through settling tanks where the sludge will be deposited and the effluent discharged through the multiple outlet mentioned. The sludge is expected to embrace upwards of 60 per cent of the suspended matter in the sewage. It is to be pumped about 2 miles to a point where it is proposed to completely neutralize it by mixing it with about 44 times its dry weight of chemical waste.

Sludge Disposal: A unique opportunity for highly effective disposal of sewage and sludge is stated by the engineers of the board, to exist due to the willingness of a caustic soda and soda ash manufacturer to permit the sludge to be admixed at their disposal lagoons with neutralizing inorganic industrial wastes. The sludge is to be pumped from the disposal plant and discharged with these wastes, which are between 40 and 50 times their volume, into extensive lagoons. The report of the chief engineer for the intercepting sewer board states that this treatment will eliminate the possibilities of offense as well as the cost and expense of operation by high grade labor, with technical supervision of expensive digestion works and drying works. It is to be recommended that formal agreement be made with the manufacturers covering this matter and definite provisions for the treatment of the sludge proposed at the lagoons. It is understood that the soda ash plant is operated continuously. The liquid wastes of this plant are estimated to be 4½ million gallons of which 700 tons dry weight is suspended solids or several times as much as appears necessary to disinfect the city's sludge which the engineers' estimate at about 1/20th million gallons per day in 1920 and 1/14th of a million gallons in 1940 with dry weights of 16 and 23 tons respectively.

Conditions for Effluent Dilution: Onondaga lake seems to afford rather favorable conditions for the disposal of settling tank effluent if properly diffused. This lake and its main outlet stream, the Oswego river below, are not used for municipal water supply. The shores of the lake are very sparsely populated and the lake itself does not seem to be used to any considerable extent for recreation. A somewhat exhaustive study by the engineers of the intercepting sewer board, of the lake's condition with respect to oxygen saturation and replenishment, seems to indicate that with proper operation and an adequate treatment plant the exhaustion of the dissolved oxygen in the upper waters of the lake may be considerably deferred and may not occur, provided the effluent is discharged into 20 feet or more of water ¼ mile from shore, until about 1945 or even still later in case the point of discharge be carried farther out into deep water of the lake. In this connection the following abstracts from the report of the consulting engineers, who devote over 150 pages to the subject, may be of interest:

Oxygen Supply: The oxygen content of the water of the lake, which is somewhat in the form of a rectangle, 4½ miles long by 1 mile wide and 42 feet deep on the average, is estimated at 834 tons; that supplied by the southern tributaries as 27 tons yearly. On the other hand the oxygen demand of the sewage after sedimentation is estimated at 1,750 tons leaving a heavy supply to be provided. This provision is to be principally met by the problematic reaeration of the lake and the diffusion of the oxygen so supplied by the seasonal overturn. There seems also some unappreciated back water flow from the floods in Seneca river which at times rises higher than the outlet and flows back into the lake. These factors must largely determine the satisfactory life of the plant as planned at present. Therefore, any saving in the plan limiting the extent to which the treatment plant removes impurities and diffuses the residual sewage waste in deep water is apt to be one of appearance only. The small margin for adequate dilution afforded at times, until the sewage leaves the Seneca river is indicated by such data as the following:

Watersheds, approximate areas:	Square Miles
Inlet tributaries, Onondaga and Ley creeks and Harbor brook	154
Mid-section tributaries, Liverpool and Nine Mile creeks	139
Tributaries at outlet N. E. end margin and lake	7
Total Onondaga watershed, except flood back flow	300
Total Seneca river watershed above Onondaga outlet	3,140
Total Oswego river at Phoenix, including Seneca and Oneida	4,950

Some Minimum Flows:	Second feet per sq. mile.
Oswego river at Oswego. For 25 days in September, 1898	0.16
Seneca, Baldwinsville. For August, 1899, 445 second feet or	0.15

Flows for several days were very much smaller than these averages.

Features of Location

The location selected for the treatment plant is near the center of the shore front of the level tract around which the city is formed. In the center of the rear portion of this area lies the Barge Canal harbor, the channel to which enters the lake about ¼ mile in a northeasterly direction. This level tract is undeveloped and remains practically a barren waste for a wide zone around the lake shore near this proposed site. The disposal site selected lies in the northwesterly angle of the quadrangle formed by the New York Central and Hudson River railroad and Delaware, Lackawanna and Western railroad on the west and south, respectively, and the former bed of Onondaga creek and Hiawatha avenue on the north and east, respectively, and lies at a distance of more than half a mile from the Barge Canal harbor or any considerably built-up portion of the city.

Structures in Detail

Overflow Chamber: In detail the first structure which the discharge from the 90-inch sewer enters after leaving the Venturi meter is the overflow chamber which, in common with the other masonry structures of the works, is to be built of reinforced concrete. In interior dimensions the structure is 40 feet long by 14½ feet wide and from 12 to 13⅝ feet high. The chamber is subdivided longitudinally by an overflow weir with a level crest running the full length of the chamber, at elevation 7. The crest is about 6 inches in width and 4¼ feet below the roof, giving an overflow weir area of 170 square feet. This weir is pierced by 3 rectangular 4 feet by 5 feet openings controlled by sluice gates, the bottoms of which are at elevation 0.33, affording, when open, an additional raceway gate area of 60 square feet. This gives a total by-pass area of 230 square feet as contrasted with the 4-foot gate of 12½-foot area leading to the treatment plant from the lower end of the chamber or the side of the weir to which the sewage from the interceptor, which has an area of 44 square feet, is admitted. Below the level of the crest or weir the channel behind the spillway has a maximum area of only 32 square feet. The area of the channel in front is 65 square feet but terminates abruptly at a wall containing a gated opening of 12½ square feet area. It is accordingly suggested that the chamber be formed to redirect the flow with the least possible disturbance and greatest economy of its velocity of approach. On account of the fact that the lake level may rise nearly a foot above the weir and cause lake water to flow into the overflow chamber, it is recommended that proper means for securing adequate flash boards to the top of the weir be provided.

Interconnecting Channel: The 4-foot sewage outlet gate from the overflow chamber and series of 4-foot pipe connections leading from it through the screen and grit chambers to the pumps seem to be somewhat restricted if a check of flow and accompanying sedimentation and obstruction is to be prevented in the main intercepting sewer. It takes nearly a 2-foot head or difference in level to force 55,000,000 gallons a day through a 4-foot circular gate. If the screens should become clogged to such an extent as to submerge the screens to elevation 4.12, the elevation of flow above the gate in the overflow chamber will need to be 2 feet higher than this, or 6.12, which is 8½ feet above the invert of the interceptor. The interceptor however is designed to deliver by gravity 55,000,000 gallons a day, with but about 3 feet over the invert. Such impounding would result in making of the interceptor a grit chamber between 1 and 2 miles long. It is recommended that the chamber below and its *passages* be made no less capacious than provided for by the plans as preliminarily approved. Should a proper combination of screen and grit chamber be desired later favorable consideration might be given to such change.

Screen Chamber: The screen chamber is placed 12 feet below the overflow chamber with which it is connected by a 4-foot pipe. It is irregularly elliptical in shape, 38 feet long by 29 feet wide, with walls 14⅛ feet high. It is subdivided into two equal channels. The main channels are 9½ feet wide at the screen emplacements. The counter-balanced cage screens are 7 feet high and 3½ feet deep but are not shown in detail. It is recommended that this chamber and its passages be made no less capacious than provided for by the plans as preliminarily approved; but the structures as shown may be further discussed. The inlet and outlet control gates are not shown in elevation or described, hence the amount of maximum screen submergence is somewhat a matter of conjecture.

Grit Chamber: The grit chamber is an open cast, 17⅛ feet deep by 18 feet wide by 59 feet long. In the bottom are arranged three channels of equal size, each depressed 2¼ feet below the elevation of the invert of the incoming and outgoing 4-foot pipe which connects it, without fall, with the screen chamber and pump house located 10 feet above and below the grit chamber. These three grit or detritus channels are each 4 feet wide and the number in use may be regulated by control gates 2½ feet wide, placed at each end of each channel. No grit removal apparatus is indicated and it is therefore recommended that a traveling crane be mounted on the parapet or side walls and an industrial railway be provided to carry the grit and screening to a place for their disposal. Should it be desired to house the screens and grit channels in the same building to facilitate operation and the removal of detritus from both, such an arrangement might not be objectionable.

Pump Station: The pump house is 58 feet long by 34 feet wide and extends 19¾ feet below the floor level. The brick superstructure, housing the motors, gate stands and offices, is 14 feet high and well lighted. No systems of heating and ventilation are shown. Five similar centrifugal pumps are shown direct, connected to motors on floor above by vertical shafts. The maximum lift from low water to tank level is but 9½ feet, or 17¾ feet, when attempting to drain the pit and at the same time surcharge the settling tanks to elevation 13 to secure head at times of high water in the lake. The minimum lift is about 8 feet. According to information furnished by the designing engineer 4 pumps will be of adequate capacity to handle 55,000,000 gallons per day, leaving 1 pump in reserve or emergency.

Sedimentation Tanks: It is planned to construct 4 radial flow settling tanks 100 feet in diameter each. They are to have conical bottoms and total wetted depths of 8⅛ feet. The screened sewage is to be delivered from the pump chamber by the pumps to a central compartment having a downturned annular opening of about 11 square feet in area, submerged about 2½ feet. From here the sewage flows radially out from the center of the tank to a sharp crested weir encircling its periphery. Here the effluent spills over into a channel leading to the deep water outlet pipe. The sludge which has settled out is to be continually pushed toward a sump at the center and bottom of the cone by a series of plows moving close to the bottom on 4 mechanically revolved submerged arms. From this sump the sludge is pumped by small pumps to the duplicate main sludge pumps in the pump house. The liquid capacity of each of the tanks is 391,600 gallons or 1,566,400 for all 4. This provides a minimum 41 minutes theoretic detention for a 55,000,000 gallon a day flow without deduction for minor tank sections inert or occupied by sludge. The report submitted on December 30 by the chief engineer states that experiments indicate that these tanks will remove as much impurities as planned and that the 5 larger tanks, holding altogether 2,800,000, were needlessly large. No data to warrant the Department in reaching so sweeping a conclusion was submitted and it does not appear likely that sufficiently convincing data could be produced by experimental methods. However, on January 25, 1921, the results of very exhaustive experiments indicative of results approaching this conclusion were presented and since it is possible to require additional units, in case inspection shows that those first installed do not accomplish the stipulated results, it would seem appropriate to approve of the tanks conditionally to the extent proposed.

Sludge Disposal System: As noted above the sludge which accumulates in the settling tank is to be pumped to 2 sludge hoppers in the pumping station. The sludge is to be pumped from these hoppers continuously through 2 miles of 4-inch force main to lagoons where it is to be mixed with chemical wastes. The sludge is to be diluted with sufficient sewage to obtain a velocity through the force main of 3 feet per second.

The sludge drains, leading from the 4 tanks to the sludge hoppers, are each to be of the same diameter as the force main. It would appear therefore that the velocity of the former will be but ¼ of that of the latter. It is suggested that consideration be given to securing self-cleansing velocities in these drains and also that gates with fire-hydrant connection between them and cleaning facilities be provided on all sludge pipes. It is also suggested that any siphons or portions of the sludge piping difficult to replace be built in duplicate, and that the sludge pumps be selected with a view to their accessibility for dissembling and cleaning, and that the low lift sludge pumps be so arranged as to secure a reversal in the direction of flow through sludge pipes when desirable. Although the danger of settlement and clogging resulting from any more than momentary cessation of pumpage in the 2-mile sludge force main appears patent, in the design, insurance against failure in operation seems somewhat lost sight of when effecting a temporary saving. It does not seem advisable to substitute 2 small 28-gallon sludge hoppers with horizontal screens on top of the hoppers for the 2,700-gallon sludge well recommended by the consulting engineers. The pumps to be used are particularly mentioned, in the report of the consulting engineers, as subject to frequent stoppage. Storage for them seems therefore essential. While the risk of shutdowns and lack of flexibility in operation entailed by the omission of the storage well for the main sewage pumps might not be serious, the omission of a provision for temporarily handling sludge during possible periods of simultaneous stoppage of pumps moving this character of material, does not appear permissible, and it is accordingly recommended that a provision be made for the storage of not less than 2,700 gallons of sludge.

Outlet Channels: At the overflow chamber the interceptor is changed in form from a 7½-foot pipe to a passageway 4 feet high by 11 feet wide, including a central partition wall 1 foot thick. For a distance of about 400 feet the portion of the sewage to be treated is diverted through the works, and is then returned to this conduit which continues to the shore. Here one side of the passageway terminates, debouching whatever sewage is diverted into it out upon the shallows at the shore line of the lake, which is shown here to have a depth of less than 1 foot at ordinary lake level for a distance out of over 400 feet and is quite possibly dry land at times. The portion of the passage on the other side of the partition is shown to discharge at the shore line into a 5-foot pipe which, with four changes of direction made under water, discharges into Lake Onondaga, 12 feet below normal water level. This discharge is effected through dispersion outlets in the terminal portion of the pipe which is to be laid on top of a submerged pier which is raised to a height several feet above the lake bed about 1,400 feet from shore.

Effluent Channel: The invert of the overflow chamber at the beginning of the partitioned passageway mentioned is at elevation 2.38, but the passage invert starts here, 2.7 feet higher, at elevation .33. The normal lake level is at elevation 1 so that the bottom of this flat passage here and all its gates will be almost continuously subject to shallow stagnant backwater. It is suggested that consideration be given to the desirability of slightly raising the grade of the passage at this point with a view to alleviating this condition. Since the tank effluent returns to this passage from a surface elevation of 9, or even 12 when necessary, and is to be returned to that portion of the passage whose contents are to discharge at a point about 2,200 feet distant; at times when the water in the lake was higher than the dry weather flow in the sewer this passage would discharge backwards into the latter. For this reason it is recommended that the uncovered part of this passage behind the weir in the overflow be walled higher or covered, and that no other ungated apertures be left below elevation 13 in the channel receiving the effluent from the settling tanks, except those of the submerged dispersion outlet.

Dispersion Outlet: The dispersion outlet shown is 5 feet in diameter and 200 feet long. No detail is given of it or of the subaqueous pile structure, 500 feet long and 17 feet high at its off shore end, which supports it. Thirteen openings are indicated on each side, all in line with the springing line, and a terminal opening 2 feet in height. It is suggested that the spring line apertures be staggered and that a terminal aperture be left in the crown to provide for the escape of gases and buoyant material. As a general proposition, under-water woodwork is extremely costly even when, as here, not particularly hazardous to construct. It is furthermore, not only subject to disintegration, corrosion of its metal bonds, contact with floating materials, navigation at extreme levels and interference with anchors, but is also expensive to construct and maintain above the depth recommended by the consulting engineers after extensive investigation. Furthermore it is not advantageously situated for subsequent prolongation to greater depth. It is accordingly recommended that the dispersion outlet be lowered at least 8 feet or that its main discharge be continued to a point at least 8 feet below the invert now shown, and it is suggested that a covered manhole opening suitable for use by a diver be placed near the end crown of the dispersion outlet pipe.

Conclusions

After a full consideration of the general and local requirements and opportunities for sewage treatment and sludge disposal, and of the essential features of design and a careful examination of the plans and data submitted, it was found that the plans in general appear to be satisfactory but that there were certain features in which modification appeared desirable before the plans were taken up for final consideration, and it was accordingly recommended that the plans be returned to the Syracuse intercepting sewer board and that they be modified in the following respects:

1. That the weir at the overflow chamber be provided with a movable crest or tight flash boards and brackets in order to permit of raising the flow line over the weir to elevation 8 when desirable.
2. That the plans as preliminarily approved be adhered to in respect to passing the contents of one branch of the dual overflow conduit through both the screen and grit chamber with no less adequate treatment and gate capacity than originally planned.
3. That a traveling crane on the parapet of the grit chamber be shown provided or other method provided for removing accumulated detritus.
4. That the combined storage capacity for sludge delivered by the low lift sludge pumps from the settling tanks be made 2,700 gallons as was provided by the approved preliminary plans.
5. That no wall of the channel into which the settling tank effluent discharged be lower than elevation 7.
6. That an ample channel not less than 400 feet long be shown excavated extending through the submerged flat from the end of the shore relief conduit to deep water in the lake.
7. That the dispersion outlet be so constructed that it will terminate with its end approximately in a horizontal position and its crown under not less than 20 feet of water at any stage of the lake.
8. That satisfactory preliminary plans be submitted providing for the method of sludge disposal finally arranged for.

Plans modified in general accordance with the recommendations of this Department were approved on February 11, 1921, and a permit was issued on this date to the Syracuse intercepting sewer board allowing the discharge of effluent from the sewage treatment and outfall works of the city of Syracuse into the waters of Onondaga lake under the following provisions in addition to the usual conditions:

> That a connection having a sectional area of not less than 19 square feet and equipped with gates to prevent back water shall be provided leading from the lower end of the grit chamber to the deep water effluent conduit.
>
> That a suitable traveling crane or other satisfactory means shall be provided for the removal of detritus from the grit chamber.
>
> That the dispersion outlet pipe between stations 20 and 27 shall be generally lowered so that the outlet end shall be 5 feet lower than shown by the plans approved this day; that 4 openings, 2 on each side, staggered, and spaced 25 feet on centers from the end, having a total combined area together with the outlet at the end of the dispersion outlet pipe of not less than 20 square feet, shall be substituted for the 26 openings shown upon the plans; and that a gas vent of approximately 5 inches in diameter, to issue horizontally at the crown of the outlet end of the dispersion outlet pipe shall be provided.

> That all the dry-weather flow of sewage collected by the intercepting sewer together with all wet-weather flow up to 55 million gallons per day shall be passed through and treated in the proposed sewage treatment and outfall works.
>
> That before the proposed sewage treatment and outfall works are constructed, satisfactory detailed contract drawings of said works, including detailed plans for the disposal of the sludge, shall be submitted to and receive the approval of this Department.

Detail contract plans for the sewage outfall works or discharge conduits for the city of Syracuse, designed in compliance with the permit issued by this Department, were approved on June 7, 1921, with the understanding that detailed contract drawings of the sewage treatment works, embracing detailed plans for the disposal of sludge, were to be submitted later. Inasmuch as the permit already granted allowed the discharge of sewage effluent from the entire works when completed, no permit was issued in connection with this portion of the contract drawings approved on June 7, 1921.

TARRYTOWN

Plans for sewer extensions in Union avenue, Sunnyside avenue and Neperan road in the village of Tarrytown, Westchester county, were approved on May 20, 1921, and a permit was issued on the same date to the board of trustees of the village to discharge sewage from the proposed extensions into the waters of the Hudson river at the foot of Josephine street, within the municipality of Tarrytown, under the following provision in addition to the usual conditions:

> That whenever required by the State Commissioner of Health, satisfactory disposal works for the treatment of the sewage of the entire village of Tarrytown shall be constructed and put in operation under and in accordance with plans which shall first be submitted to and receive the approval of said Commissioner.

TUCKAHOE

Plans for sewer extensions on Armour Villa avenue, Summit street and Marble place in the village of Tuckahoe, Westchester county, were approved on April 23, 1921, and a permit was issued on that date to the board of trustees of the village to discharge sewage from these extensions into the waters of the Hudson river through the Bronx Valley sewer within the city of Yonkers, under the following provision in addition to the usual conditions:

> That the existing sewer on Garrett street, into which the proposed sewer on Armour Villa avenue is proposed to discharge, be relieved or increased in size whenever necessary or required by this Department.

TURIN (T) (School District No. 9)

Plans for a sewage disposal plant consisting of a settling tank, a dosing chamber and a subsurface irrigation system to serve the school of School District No. 9 of the town of Turin, located at the village of Turin, Lewis County, were approved by the State Engineer on December 12, 1921, and a permit was issued by the State Commissioner of Health on December 16, 1921, to the board of trustees of this district to discharge effluent from the proposed plant into the ground waters tributary to Mill creek on the school property within the town of Turin, under the usual conditions.

VILLENOVA (T) (Villenova Cheese Factory Company)

A permit to discharge effluent from a disposal plant to serve the cheese factory of the Villenova Cheese Factory Company, located about one mile west of South Dayton in the town of Villenova, Chautauqua county, into the waters of Conewango creek, within the town of Villenova, was granted to this company on June 30, 1921, under the following provision in addition to the usual conditions:

> That no sewage or wastes containing human excreta or washings and no whey, skim milk, buttermilk or other wastes containing any considerable amount of putrescible organic matter shall be discharged into the disposal plant or Conewango creek.

WARSAW

Amended plans for sewers and sewer extensions in the village of Warsaw, Wyoming county, were approved by the State Engineer on November 3, 1921, and a permit was issued by the State Commissioner of Health on November 10, 1921, to the trustees of the village of Warsaw, to discharge sewage from the proposed sewers on Court and other streets and through private rights of way into the waters of Oatka creek, within the village of Warsaw, under the following provision in addition to the usual conditions:

> That a thorough study be made of the entire system of sewerage and sewage disposal of the village of Warsaw, and that on or before November 1, 1922, plans for a system of sewers which shall serve the entire village, into which only sanitary sewage shall be admitted, be submitted to the State Engineer for approval.

WATERTOWN

Plans for sewer extensions on Haley street between Myrtle avenue and Washington street in the city of Watertown, Jefferson county, were approved by the State Engineer on August 30, 1921, and a permit was issued by the State Commissioner of Health on August 31, 1921, to the Common Council of this city to discharge sewage from these proposed extensions into the water of the Black river through the existing outlet at the lower end of Engine street, within the city of Watertown.

WESTMORELAND (T) (Bartlett Milk Station)

A permit to discharge effluent from an industrial waste disposal plant to serve the milk station of the Bartlett Milk Station, located in the hamlet of Bartlett, in the town of Westmoreland, Oneida county, into the waters of a tributary to Jones creek, within the town of Westmoreland, was granted to H. J. Wolfe on June 7, 1921, under the following provision in addition to the usual conditions:

> That no domestic sewage or washings containing human excreta and no whey, buttermilk, skim milk or other wastes containing any considerable amount of organic matter, shall be discharged into or pass through the disposal plant.

WILSON

Plans for a sewer system and for a sewage disposal plant consisting of a two-story settling tank, an effluent chlorination apparatus and a sludge drying bed and an outfall sewer with submerged discharge to serve the village of Wilson, Niagara county, were approved by the State Engineer on November 25, 1921, and a permit was issued by the State Commissioner of Health on

December 13, 1921, to the board of trustees of the village to discharge effluent from this plant to be constructed in connection with this sewer system into the waters of Lake Ontario, near the mouth of Twelve Mile creek, about 600 feet from shore, within the village of Wilson, under the following provisions in addition to the usual conditions:

That the chlorinating apparatus to be installed shall have a capacity of not less than 15 parts of chlorine per million gallons of sewage by weight and that chlorine shall be applied to the effluent at a point not less than 5 feet below the surface of the effluent at the rate of not less than 5 parts chlorine per million gallons by weight and in such other or additional amounts as the State Commissioner of Health may from time to time hereafter designate.

WOODRIDGE

Plans for a sewer system and sewage treatment plant, consisting of settling tanks and sprinkling filters, for Woodridge, Sullivan county, were approved on May 14, 1921, and a permit was issued to the board of trustees on the same date to discharge effluent from this proposed treatment plant into the waters of Sanbury river at a point below the dam of Wood's pond, within the town of Fallsburg, under the following provisions in addition to the usual conditions:

That no flushing or other inlet from any creek to the sewer be provided.

That properly guarded vents for the sludge beds be installed at points outside of the surface of the beds.

That before the construction of any street sewers not shown on these detailed plans, plans for such sewers shall be submitted to and receive the approval of this Department.

That whenever necessary or required by the State Commissioner of Health, additional units or portions of the works shown on the plans approved this day shall be constructed and put into operation.

YORKTOWN (T) (Mohegan Inn Corporation)

Plans for a sewage disposal plant consisting of a liquefying tank followed by leaching cesspools, six to be constructed at once; to serve the summer hotel of the Mohegan Inn Corporation, located in the hamlet of Mohegan Inn, near Mohegan lake, in the town of Yorktown, Westchester county, were approved on April 6, 1921, and a permit was issued on the same date to the Mohegan Inn Corporation to discharge effluent from this proposed plant into the ground waters tributary to the outlet from Mohegan lake, within the town of Yorktown, under the following provision in addition to the usual conditions:

That the effluent pipe shall be provided with manholes or cleanouts at all angle points and shall have a grade of not less than 1 foot in 300.

GENERAL INVESTIGATIONS RELATING TO SEWERAGE AND SEWAGE DISPOSAL

During the year of 1921 a large number of matters relating to the collection and disposal of sewage were brought to the attention of this department either by direct complaints from persons affected or by local authorities who requested assistance and advice in meeting their problems.

A comprehensive investigation of the municipality in nearly every case is made by a representative of the Division of Sanitation and a report prepared describing the existing sewerage conditions and method of disposal of the sewage and recommending steps to be taken to provide a permanent remedy for the problem. Although this department is without the power to compel the installation of systems of sewerage and sewage disposal and consequently the completion of its work is curtailed, yet. in many instances effective action is taken by the local authorities on the advice and at the instigation of this department.

The reports of the investigations made by this department in a few important cases which have come before it during 1921 are given below and a list is appended of all other cases.

EASTWOOD

An investigation of conditions of sewerage and sewage disposal in the village of Eastwood, Onondaga county, N. Y., was made by Mr. W. C. Emigh, assistant engineer in this Department, on January 21, 1921. This investigation was undertaken as a result of a communication from the clerk of the village of Eastwood on behalf of the board of trustees, in which it was stated that difficulty had been experienced in the operation of the sewage pumping plant and disposal works and in which advice was requested relative to the method of handling the situation.

In the year 1913 plans were approved by this Department for sewerage and sewage disposal for the village of Eastwood. These plans included a sewage pumping plant and two sewage disposal plants. The topography of the area within the village is such that it was considered more desirable to treat the sewage in two plants than to conduct it entirely to one plant. The sewer system was designed to care for a population of 10,000 and the original disposal plant construction was intended to treat the sewage from a maximum population of 1,000 at each plant. A portion of the village was so low as to require that the sewage from it be pumped into a higher sewer. Sewage from the residential part of this low, level section is collected in sewers laid in the streets but is conveyed to the pumping station in an 8-inch sewer laid on private property and extending for a distance of about 2,000 feet parallel and closely adjacent to the right of way of the New York Central railroad. This sewer is laid on a grade of .5 per cent in low land which at times is saturated with ground water.

In addition to the domestic sewage reaching the pumping plant, as above described, sewage and industrial wastes from the plants of the Pierce, Butler and Pierce Company and the Syracuse Rendering Company are conveyed to the pumping plant. Normally about 40 toilets, 20 lavatories and a number of shower baths are in use. There is also a kitchen used for preparing lunches which are served to employees. The company purchases about 500,000 gallons of water per month from the Syracuse Suburban Water Company. The plant of Syracuse Rendering Company is located within the village limits at a distance of about ¼ mile from the pumping station. An 8-inch cast-iron pipe with leaded joints extends from the plant to the village system.

The wastes are said to consist principally of sanitary sewage and cooling water. On at least two occasions, however, owing to fire or other causes considerable quantities of organic matter have overflowed from the vats into the drains and thence into the sewers. The drainage from a building in which hides are salted and cured also discharges into the sewer.

At the time of the inspection, owing to the clogging of the sewer leading to the village pumping plant, the sewage was rising through the tops of manholes on the premises of the Rendering Company and flowing over the surface of the ground into a ditch in which it flowed a short distance to a second ditch on the railroad right of way. The sewage coming from the building in which hides are cured was pooled upon the surface of the ground. The engineer of this Department found a considerable quantity of organic matter, apparently consisting largely of fleshing from the hides, which had settled out of the sewage in these pools. The manager of the plant stated that formerly the waste containing these fleshings had been evaporated but that the practice had been discontinued on the ground of impracticability.

Industrial wastes of this class contain impurities largely in excess of the quantities contained by the average domestic sewage. There can be little doubt that the discharge of this waste into the village sewer not only tends to cause difficulty with the operation of the pumping plant but throws an unduly heavy load upon the disposal plant. In view of the excess strength of this waste over that of ordinary domestic sewage, it appears advisable that the Syracuse Rendering Company install a plant to effect a preliminary treatment of their industrial wastes before discharge into the village system. Such a plant should include one or more tanks for the settlement of the wastes with the outlet so constructed as to trap any greases which may enter the sewer.

The village sewage pumping plant is located on Nichols street. The sewage reaching it first enters a circular well in which it passes through a horizontal bar screen. The well is 15 feet in diameter with a depth below the operating floor of 25 feet. This floor is about 3 feet below the ground surface. A concrete partition wall is constructed on the diameter of the well. The sewage after passing through the bar screen flows through two ports in the partition wall at the well floor level into the pump chambers. The two pump chambers are separated from each other by a concrete wall also provided with an interconnecting port. Each of the three ports is fitted with a gate operated from the main floor. A pump is installed in each of the pump chambers. From the pumps the sewage is forced through about 350 feet of cast-iron pipe to a point on Burnet avenue from which point it flows by gravity a distance of 3,000 feet to the southerly disposal plant.

The pumping equipment consists of two centrifugal sump pumps. The smaller is a 4-inch pump of 400 gallons per minute rated capacity at a speed of 1,150 r. p. m. This pump is driven by a direct connected 10 horsepower, 3 phase, 220 volt, 1,150 r. p. m. induction motor. Definite data could not be obtained at the time of the investigation regarding the size of the largest unit, but it was thought to be a 6-inch pump. It is driven by a 15-horsepower motor. A 16-horsepower Fairbanks gas engine, 350 r. p. m., connected by bevel gears with the pump shaft is also provided for emergency use in case of failure of the electric power.

At the time of the investigation it was learned that for several years considerable trouble had been experienced with the operation of the pumping plant. It is reported that large solids reach the plant and that these solids interfere seriously with the operation of the pumps and especially with the smaller of the two units. It was found that the larger pump had been dismantled for repairs and had not been reassembled. Sewage was standing in the well to a depth of about 14 feet, thus making it impossible to examine the smaller pump. The smaller unit was operating at the time but in an attempt to decrease the head against which it was pumping it had been disconnected from the pressure sewer and was discharging onto the surface of the highway through a line of fire hose extending through a window. Although the rate of pumping was not measured it was evident from the volume of the stream issuing from the hose that the pump was delivering only a small fraction of its rated capacity.

The sewage as it flowed upon the highway appeared to be much diluted. The plant of the Pierce, Butler & Pierce Company was contributing only a small quantity of sewage at the time, due to restricted operation. No sewage was reaching the pumping station from the rendering company plant, due to clogging of the sewer, as noted. It therefore appeared probable that the greater part of the sewage pumped resulted from ground water infiltration in the line of sewer paralleling the railroad, as previously described.

From this inspection it is evident that the pumping plant should be thoroughly overhauled. Whether or not the present pumping equipment can be placed in condition to satisfactorily handle the sewage reaching it could not be determined by our engineer owing to the depth of sewage in the well at the time. It is advisable that the mechanical equipment be carefully inspected by an engineer familiar with this type of machinery to determine the extent of the necessary changes.

It is further advisable that means be found to prevent the considerable ground water infiltration which apparently existed at the time of the inspection. The entrance of this ground water into the pump well not only increases the cost of pumping but throws an unnecessary burden upon the plant which at times may combine with the sanitary sewage and industrial wastes entering the well to overtax the capacity of the equipment. A careful inspection should be made of the sewers to determine the location of the points of infiltration. A survey should also be made of all houses the sewage from which reaches the pumping plant, to discover any roof connections which may have been made to the sewer. Such a study would show the most practical method of correction of the conditions, whether relaying of a section of sewer, the substitution of bituminous joints or the replacement of a section of the sewer by iron pipe. After the determination of the proper method, the work of correction should be undertaken at as early a date as conditions permit.

The two village disposal plants were designated and have been constructed along similar lines and as no serious difficulties have been experienced with the operation of the northerly plant only the southerly plant into which the sewage is pumped was inspected. This plant consists of a settling tank of the two story Imhoff type, a dosing siphon and sludge drying bed and a sprinkling filter. The sewage chamber of the settling tank is designed to afford a detention of 2½ hours when receiving the sewage from 1,000 people under the assumed per capita consumption. The sewage chamber is rectangular but the sludge chamber is circular in plan. Sludge storage is provided for a period of six months. It was found that the scum was frozen in the gas vent compartment and that some scum was floating on the surface of the sewage in the sewage chamber.

From the settling tank the sewage after passing over a weir flows into a dosing chamber adjacent to the tank. An 8-inch automatic siphon is installed in the chamber. Upon discharge from the dosing chamber, the sewage flows under pressure a distance of about 300 feet to the sprinkling filter. This filter is 41 feet 5 inches by 58 feet 6 inches in plan and has a depth of 5 feet 3 inches. The filtering medium is crushed stone ranging from 1½ to 2½ inches in diameter. The eleven nozzles provided are staggered and spaced on 13-feet 6-inch centers. Of these nozzles, two, at the time of the inspection, were without spindles and in consequence of this condition were throwing large streams onto the bed causing pooling. The remainder of the nozzles appeared to be operating satisfactorily with the exception of one, the head upon which was much less than upon the others. Although no final settling tank is provided the effluent, as far as it could be observed in the effluent manhole, appeared to be fairly clear.

From the preceding brief description of the condition of the disposal plant it is evident that greater care and attention should be exercised in its operation. The nozzles should at all times be kept in operating condition and any obstruction which occurs in the pipes or nozzles should be promptly removed. Any scum which collects upon the surface of the sewage in the sewage chamber of the tank should be skimmed off and the gas vents should be kept open to allow the escape of gases.

It is to be noted in connection with the disposal plants that each was originally designed to care for the sewage from a maximum of 1,000 persons. As the present population is said to be not less than 2,500 persons and as a considerable quantity of sewage reaches the plants from the industrial concerns previously described together with a quantity of ground water, it appears probable that the present plants are overtaxed. The original design provided for additional units as these should become necessary. In order to determine whether either or both of these plants are actually overtaxed a careful survey should be made of the system contributing to each plant together with observations of the quantity of sewage flowing from the industrial establishments and the volume of ground water infiltration. The scope of the recent inspection did not permit an investigation into these details nor is it possible for this Department to undertake such a study. The village authorities should, however, instruct the village engineer to make a careful study of the situation and if found that the existing plants are operating beyond their capacity, the additional construction necessitated thereby should be undertaken at an early date.

As a result of the investigation and after a careful consideration of the conditions of sewerage and sewage disposal in the village of Eastwood, it was pointed out in a report dated February 9, 1921, that the difficulty experienced in the operation of the pumping plant and sewage disposal plant was due to:

1. The inclusion in the sewage reaching the pumping plant of industrial wastes containing large quantities of organic matter much of which is in the form of solids.
2. Inadequate pumping equipment at the village sewage pumping station.

It was therefore recommended:

1. That the village of Eastwood require the Syracuse Rendering Company to install a suitable sewage treatment plant to afford a preliminary treatment of their wastes before discharge into the village sewers.
2. That the village authorities of Eastwood instruct their engineer to carefully examine the condition of the pumping equipment at the sewage pumping station and that if the present machinery is found to be inadequate new equipment be installed at the earliest possible date.
3. That the village authorities of Eastwood instruct their engineer to make a careful survey of the quantity of sewage reaching each of the two village disposal plants to determine whether or not these plants are overtaxed and that if the plants are found to be operating beyond their capacity new units be added as required.
4. That a careful investigation be made to determine the point or points of entrance into the sewer system of ground or rain water and that proper means be adopted to exclude these waters from the system.

Copies of the report on the investigation were sent to the Sanitary Supervisor of the district, the President and Board of Trustees of the village of Eastwood and the Syracuse Rendering Company.

RICHFIELD SPRINGS

An investigation of the disposal of sewage from Richfield Springs and of the alleged pollution of ice cut from Canadarago lake and used by residents of the village of Schuyler Lake, N. Y., was made on July 7, 1921, by Mr. A. I. Howd of this Division as a result of a complaint made to this Department on June 17, 1921.

Richfield Springs is an incorporated village, having a population of about 1,400, located in the northern part of Otsego county. The village is located at the head of Canadarago lake, a body of water about 3.8 miles in length and varying from about 0.5 to 1.2 miles in width. The sewage of the village, including the wastes from a milk station and certain mills, is discharged into Ocquionis creek, the inlet of the lake. Schuyler Lake is an unincorporated village having a population of about 350, located in the town of Exeter at the foot of Canadarago lake, 6 miles south of Richfield Springs.

The matter of the pollution of Ocquionis creek by sewage and wastes from the village of Richfield Springs has been before the Department in the past, a representative of the Department having made an investigation on January 30, 1909. The report upon that investigation, dated February 8, 1909, pointed out that the stream was flowing full yet the influence of the sewage discharged into it was plainly visible for more than 1/3 the width of the stream for several hundred feet down stream from the point of discharge. It was also pointed out that owing, doubtless, to the comparatively high water stage of the stream and to the low temperature no nuisance could be noticed in the vicinity of the point of discharge of the sewage at the time of that inspection, but that it was reasonable to assume that during the warm season when dry weather conditions prevail and the amount of sewage discharged at this point was over three times the discharge at that time the stream would be seriously polluted.

Under date of February 19, 1909, the trustees of the village of Richfield Springs made application to this Department for the issuance of a permit allowing the discharge of sewage from the village into Ocquionis creek. On July 15, 1909, permission was given to the board of trustees of Richfield Springs to discharge sewage from the main outlet sewer of the village sewer system into Ocquionis creek, at the point of outlet near the grounds of the Richfield Springs Agricultural Society under the following conditions:

" I. That this permit shall be revocable at any time or subject to modification or change when in the judgment of the State Commissioner of Health such revocation, modification or change shall become necessary or desirable by reason of the condition of pollution of the waters of Fish Creek or of Canadarago Lake.

" II. That whenever required by the State Commissioner of Health, complete plans satisfactory to this Department for the separation, collection and treatment of the entire sanitary sewage of the village of Richfield Springs shall be submitted to this Department for approval; and any or all portions of the sewage disposal plant and intercepting sewers shown by said plans that may be stipulated at the time of approval of said plans shall be constructed and put in operation within the time then specified."

The present investigation disclosed the following facts in regard to the pollution of Ocquionis creek. The village sewers receive storm water as well as domestic sewage and trade wastes and have their main point of discharge in Ocquionis creek near the fair grounds of the Richfield Springs Agricultural Society. Although it was impossible to locate the exact point of discharge of the outfall sewer at the time of the inspection, nevertheless, the effect of the sewage discharge was plainly evident. The creek is very sluggish and the flow is hardly perceptible. The waters of the stream for a considerable part of its length below the probable point of sewage discharge, were wholly or in part covered with a thick, black scum and large particles of black sludge which had evidently arisen from the bed of the stream. The stream was in a grossly polluted and very insanitary condition. Other village sewers discharge smaller amounts of sewage into the creek at different points within the village.

The wastes from the factory of the Borden's Farm Products Company are discharged into the village sewer system. In the past the milk received at this plant has been separated, the cream shipped and the skimmed milk made into casein. The whey has been discharged into the sewers and it is alleged that large quantities of skimmed milk have also been discharged into the sewers which may be responsible to a certain extent for the insanitary conditions of the creek.

The wastes from a mill of the Utica Knitting Company, engaged in the manufacture of ladies and children's underwear, are discharged into the creek at a point in the village. The wastes consist principally of bleaching and washing waters and amount to about 100,000 gallons daily. The wastes probably contain variable amounts of caustic soda, bisulphite, bleaching oil, chlorine and sulphuric acid. The mill was in operation more or less during the past winter and at the time of the inspection was in full operation.

The superintendent of the mill stated that no dyeing had been done at this mill for several years. The discharge of wastes discolored the stream somewhat at the point of discharge, but apparently no conditions of nuisance were created.

Schuyler Lake village was visited and the complainant was interviewed. Several cakes of ice taken at random from the ice-house of the complainant were inspected. Each cake of ice examined appeared to contain a number of light pink spots in the center of which dark brown substances were noticeable. As the ice was cut away to examine the brown substances, the pink coloration became less and less apparent and finally could not be noticed as the dark brown matter was reached. The matter seemed to be of a greenish-brown color, resembled decayed algae growths and a slight but distinct disagreeable odor resembling decaying algae was detected upon close observation. Samples of ice containing the pink coloration and the brown substances were collected and later examined under the microscope at this office. The examination confirmed the observations in the field that the brown substances were algae growths or aquatic plants. These particular growths belong to the Chlorophycoac and are of the Ulothrix genera. No sewage or particles of sewage were noticeable in the ice.

In view, however, of the polluted and insanitary condition of Ocquionis creek which is caused principally by the discharge of sewage and wastes from the sewer system of the village of Richfield Springs, the village should, in accordance with the provisions of the permit issued to them by this Department on July 15, 1909, provide as soon as possible for the separation, collection, and treatment of all the sewage of the village before it is discharged into Ocquionis creek. The village authorities should employ a competent sanitary engineer to prepare plans for the separation, collection, and treatment of the sewage and submit the plans at an early date to the State Engineer and Surveyor for approval in accordance with the provisions of Chapter 510 of the Laws of 1921. At the same time application should be made to this Department for permission for the discharge of effluent from such treatment works into the waters of the State.

As a result of this inspection it seems that the alleged pollution of ice cut from Canadarago Lake and used by residents of Schuyler Lake is not caused by dye-stuffs and sewage but the ice does contain algae growths, or aquatic plants. The presence of algae in the ice might have been caused by several conditions, such as cutting the ice in shallow water containing algae growths or on account of the poor ice season of the past winter which caused intermittent freezing and thawing of the ice. Under these conditions the algae might have been washed onto the ice in the lake during a thaw or freshet and then frozen in the ice during a subsequent cold spell so that algae could not be expelled from the ice during the natural process of freezing.

Canadarago Lake is of sufficient size and capacity to provide a long period of storage of the water and the sewage discharged into the upper end of the lake is subject to natural processes of purification by sedimentation and oxidation before it reaches the lower end of the lake. As to the actual danger from the use of ice cut from waters that received pollution, it may be stated that in the process of freezing a very large percentage of impurities, including bacteria are mechanically excluded, that is the number of bacteria in the ice is only a small percentage of the number of bacteria in the water from which the ice is formed or taken. It may be stated further that when ice is stored for any considerable period, bacteria that were originally present die off very rapidly. Experience has uniformly shown that in ice that has been stored these bacteria have been reduced to such an extent that after a period of say two months, substantially all of the bacteria have been destroyed. This means that the purifying effect of freezing and low temperature under the conditions found in ice is ordinarily as great as that accomplished by artifical water purification processes. It seems, however, that ice cut from Canadarago Lake at times contains algae which render it objectionable. It would therefore seem advisable not to use the ice for cooling by immersion and in the future to cut the ice in portions of the lake free from algae growths.

In view of the above facts the following conclusions were made in a report dated August 26, 1921:

1. That the discharge of sewage and wastes from the main outfall sewer of the village of Richfield Springs causes gross pollution of Ocquionis creek and creates very insanitary conditions.
2. That the discharge of large quantities of skimmed milk or other wastes having large quantities of decomposable organic matter from the factory of the Borden's Farm Products Company into the village sewers is apparently responsible to a certain extent for the creation of the insanitary condition of the creek.
3. That the samples of ice cut from Canadarago Lake, used by residents of Schuyler Lake, and shown our representative, contained algae growths belonging to the Chlorophyceae and of the Ulothrix genera.

It was therefore recommended:

1. That the village of Richfield Springs provide as soon as possible for the separation, collection, and treatment of all the sanitary sewage of the village before its discharge into Ocquionis creek.
2. That the village employ a competent sanitary engineer to prepare plans for the separation, collection, and treatment of all the sanitary sewage of the village and submit the plans to the State Engineer and Surveyor for approval and make application to this Department for a permit to discharge effluent from such treatment works in accordance with the provisions of Chapter 510 of the Laws of 1921.
3. That the village authorities require that the Borden's Farm Products Company discontinue the discharge of skimmed milk and other wastes containing large amounts of decomposable organic matter into the village sewers.

Copies of this report were sent on August 30, 1921 to the local boards of health of the town of Exeter and the village of Richfield Springs, to the Sanitary Supervisor of the district, to the village authorities and to the complainant. On September 30, 1921 the president of the village and members of the board of trustees of the village of Richfield Springs called at the Department and conferred with the Director of the Division of Sanitation in regard to the disposal of sewage of the village. The village officials agreed to employ an engineer at once to prepare plans for the disposal of the sewage and submit the plans to the State Engineer for approval.

WARSAW

An investigation of the sewerage conditions of the village of Warsaw, Wyoming county, with special reference to the pollution of Oatka creek by the discharge of untreated sewage from the village was made on July 18, 1921 as a result of complaints from residents of the village.

The village is provided with a public water supply and has a public sewerage system which covers the greater portion of the eastern half of the village and part of the western section of the village. Plans and specifications for a public sewer system including general plans for sewage disposal were approved by this Department on January 28, 1902. These plans also showed the combined sewers which had been constructed before the plans were approved in the eastern part of the village. These combined sewers covered the greater portion of the eastern half of the village and discharged into Oatka creek through a 36-inch sewer between Court street and North street extended, and through a 24-inch sewer near the foot of North street extended. The system for the western section of the village and for a portion of the village east of the creek was designed on the separate plan, and provided for intercepting the dry weather flow of sewage from the 36-inch and 24-inch existing combined sewers at Mechanic street.

The approved plans also provided for carrying the domestic sewage from the section west of Oatka creek across the creek to the eastern side of the creek at Court street through a 15-inch sewer. This sewer, after increasing in size to 18 inches, was shown extending east on Court street to Mechanic street where it was to connect with the sewers serving the eastern portion of the village. From the intersection of Mechanic and Court streets the domestic sewage and the dry weather flow of the combined sewers were to be conveyed through an 18-inch sewer in Mechanic street and through private property to Culver avenue. At this point the sewer was to be increased in size to 20 inches in diameter and was to extend to the proposed disposal plant consisting of a septic tank and contact beds to be located on the east side of Oatka creek near the northerly boundary line of the village. A note on the approved plans indicated that the disposal plant was to be constructed when required by the State Department of Health. The plans also show a storm water sewer on West Buffalo street and in Oak street discharging into the creek at the Buffalo street bridge.

The recent inspection showed that the approved plans have not been followed very closely in the construction of the domestic or separate sewers, but many of these sewers have been and are being constructed in general accordance with amended plans recently prepared by consulting engineers for the village. These revised plans, however, were not submitted to nor approved by this Department as required by the Village Law. A domestic sewer has been constructed in Maples street and West Court street. This sewer serves some 25 houses and discharges into Oatka creek at the Court street bridge. Another sewer has been constructed in West Buffalo street. This sewer, instead of extending west on Buffalo street to Maples street thence on Maples street to Court street and east on Court street and across the creek to Mechanic street as provided by the original and approved plans extends through private property west of the public school house to Court street and empties into the creek opposite the house of one of the complainants some 50 feet north of the Court street bridge. Only two or three connections including the school house have thus far been made to this sewer, which has just been completed. Although no nuisance was created by the discharge from this sewer at the time of the inspection, it is designed to serve considerable population and a serious nuisance will in all probability be created when the school house opens in the fall and the houses along the sewer are all connected. Domestic sewers are also being constructed in accordance with the revised plans referred to in East Buffalo street, Murray street and through private property east of Oatka creek, and it seems that the village authorities contemplate temporarily emptying the sewage from these sewers into the creek near Court street through a new outlet. No new sewer outlets into the creek within the developed sections of the village should be constructed, and immediate steps should be taken to extend the existing outlets at Court street to a point below the built-up portion, pending the construction of the village sewage disposal plant. Considering the number of new sewers under construction and the consequent increase in the amount of sewage discharged into the creek the conditions of pollution of Oatka will soon be, if it is not already, so serious that it will be necessary for the village to provide for at least a partial treatment of its sewage.

The construction of the sewers referred to above constitutes a violation of the Village Law and of Article V of the Public Health Law, inasmuch as the plans for the sewers recently constructed and under construction have not been submitted or received the approval of this Department, and since no permit for the discharge of sewage into the creek at Court street has been issued to the village. The inspection also showed that the lower portion of the 36-inch combined brick sewer below Court street, shown by the approved plans is not covered, but the sewage from this sewer flows in an open ditch to the creek, a distance of a few hundred feet. The open section of the sewer is only two or three hundred feet from the rear of the houses on East Mechanic street and gives rise to objectionable conditions. This section of the sewer should be covered as soon as possible.

The report upon the investigation dated July 30, 1921 contained the following conclusions:

> 1. That the village has constructed sewers under amended plans not approved by this Department, thereby violating the village law.
>
> 2. That two new sewer outlets into Oatka creek have been constructed by the village at Court street and that sewage is discharged therefrom in violation of the Public Health Law, since no permit for the discharge of sewage at this point has been issued by this Department.
>
> 3. That objectionable conditions are created by the open 36-inch combined sewer near Mechanic street, and by the discharge of raw sewage into the creek in close proximity to dwellings in the village.
>
> It was therefore recommended:
>
> 1. That immediate steps be taken to cover the existing 36-inch sewer below Court street and to extend the 2 outlets at Court street to points below the built-up section of the village pending the interception and disposal of the entire sanitary sewage of the village.
>
> 2. That the village authorities at once prepare plans for both past and proposed amendments to the original approved plans and for any other changes in its sewage system, and that such amended plans be submitted to the State Engineer for approval as required by chapter 510 of the Laws of 1921, and that application be made to this Department for permit to discharge from new outlets.
>
> 3. That steps be taken by the village authorities to provide for the interception and disposal of its sewage as soon as possible.

Copies of this report were sent on August 5, 1921, to the president of the village of Warsaw, to the local health officer, to the sanitary supervisor of the district and to the complainant. On August 11, 1921, a communication was received from the village clerk stating that the board of trustees of the village voted to carry out the recommendations of the report and had engaged an engineer to prepare plans. Plans for sewers and sewer extensions for the village were approved by the State Engineer on November 3, 1921, and on November 10, 1921, permission was given by this Department to the board of trustees of the village of Warsaw to discharge sewage from the proposed sewers into Oatka creek on certain conditions.

In addition to the above, inspections were made and reports written in matters relating to sewerage and sewage disposal at the following places: Colonie (town), Menands (three inspections), Cornwall, Glenville (town), Alplaus, Guilderland (town), McKownville, Hastings-on-Hudson (two inspections). Long Beach, Norfolk, Oyster Bay (town), Farmarde Farms and Pine Hill.

PROTECTION OF PUBLIC WATER SUPPLIES

ENFORCEMENT AND ENACTMENT OF RULES AND REGULATIONS DURING 1921 FOR THE SANITARY PROTECTION OF THE PUBLIC WATER SUPPLIES OF NEW YORK STATE

The enforcement and enactment of rules and regulations for the protection from contamination of public water supplies in accordance with the provisions of Article V of the Public Health Law is one of the most important functions of the State Department of Health. This law outlines in detail the procedure to be followed in the enforcement of the rules. In general the local authorities in charge of the water supply are largely responsible for the carrying out of the procedure in conjunction with the State Department and the local board of health.

Of the 535 public water supplies in the State, 89 are now protected by such rules and regulations and requests have been received from the authorities in charge of 4 other supplies, which will be enacted as soon as the necessary field investigation can be made. Rules and regulations have been enacted in 1921 for the protection of the public water supplies of Beacon, Brocton, Canton, Newark and Nunda and tentative rules have been prepared for Lake Placid and Liberty. Requests have been received during the year for the enactment of rules and regulations for the protection of the public water supplies of Champlain, Collins, Hyde Park and Wappingers Falls.

BEACON

Rules and Regulations

The rules and regulations hereinafter given, duly made and enacted in accordance with the provisions of sections 70, 71 and 73 of chapter 45 of the Consolidated Laws (Public Health Law), as hereinbefore set forth, shall apply to all natural and artificial reservoirs and to all watercourses tributary therto or ultimately discharging into said reservoirs, these bodies of water being sources of the public water supply of the city of Beacon, Dutchess county, New York. The term " reservoir " wherever used in these rules is intended to mean and refer to the " Beacon Pocket " and " Melzingah " storage and impounding reservoirs which serve as sources of this public water supply. The term " watercourse " wherever used in these rules is intended to mean and include every spring, pond (other than artificial reservoirs and filter basins), stream, ditch, gutter or other channel of any kind, the waters of which when running, whether continuously or occasionally, eventually flow or may flow into the reservoirs tributary to the public water supply of the city of Beacon.

Wherever a linear distance of a structure or object from a reservoir or from a watercourse is mentioned in these rules it is intended to mean the shortest horizontal distance from the nearest point of the structure or object to the high-water mark of a reservoir or to the edge, margin or precipitous bank forming the ordinary high-water mark of such watercourses.

Privies Adjacent to any Reservoir or Watercourse

1. No privy, privy vault, pit, cesspool or any other receptacle of any kind used for either the temporary storage or the permanent deposit of human

excreta, shall be constructed, placed, maintained or allowed to remain within 100 feet of any reservoir or watercourse tributary to the public water supply of the city of Beacon.

2. No privy, privy vault, pit, cesspool or any other receptacle used for the permanent deposit of human excreta shall be constructed, located, placed, maintained or allowed to remain within 300 feet of any reservoir or any watercourse tributary to the public water supply of the city of Beacon.

3. No cesspool, pit or other receptacle of any kind used for the temporary storage of human excreta or sewage shall be constructed, located, maintained or allowed to remain between the limiting distances prescribed by Rule 1 and the limiting distances prescribed by Rule 2, unless said cesspool, pit or other receptacle is so arranged and equipped that the said excreta or sewage are at once removed by pump or other satisfactory means through watertight pipes or conduits to some proper place of ultimate disposal, as hereinafter provided, or unless suitable removable vessels or receptacles for the temporary storage of said human excreta or sewage are provided and at all times maintained in an absolutely watertight condition and in such manner as to permit of convenient removal of said excreta or sewage to some place of ultimate disposal as hereinafter set forth.

4. The excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall be removed and the receptacles thoroughly cleaned and deodorized as often as may be found necessary to maintain the privy in proper sanitary condition and to effectually prevent any overflow upon the soil or upon the foundation or floor of the privy. In effecting this removal the utmost care shall be exercised that none of the contents be allowed to escape while being transferred from the privy to the place of disposal, hereinafter specified, and that the contents while being transferred from the privy to the place of disposal, shall be thoroughly covered and that the least possible annoyance and inconvenience be caused to occupants of the premises and the adjacent premises.

5. Unless otherwise specifically ordered or permitted by the State Department of Health, the excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall, when removed be disposed of by burying in trenches or pits at a depth of not less than 18 inches below the surface and at some point off the watersheds of the reservoirs and watercourses tributary to the public water supply of the city of Beacon.

6. Whenever, owing to the character of the soil or of the surface of the ground, or owing to the height or flow of subsoil or surface water, or other special local conditions it is considered by the State Commissioner of Health that excremental matter from any privy or aforesaid receptacle, or from any trench or place of disposal, or the garbage or wastes from any dump, may be washed over the surface or through the soil in an imperfectly purified condition into any reservoir or watercourse, then the said privy or receptacle for excreta, or the trench or place of disposal, or the said garbage or waste dump, shall, after due notice to the owner thereof, be removed to such greater distance or to such place as shall be considered safe and proper by the State Commissioner of Health.

Sewage, House Slops, Sink Waste, Etc.

7. No house slops, bath water, sewage or other excretal matter from any water closet, privy, cesspool or other sources, shall be thrown, placed, led, conducted, discharged or allowed to escape or flow in any manner either directly or indirectly into any reservoir or any watercourse tributary to the public water supply of the city of Beacon, nor shall any such matter be thrown, placed, led, discharged or allowed to escape beneath the surface except into watertight receptacles, the contents of which are to be removed, as provided by Rule 4, within 300 feet of any reservoir or watercourse tributary to the public water supply of the city of Beacon.

8. No garbage, putrescible matter, kitchen or sink wastes, refuse or waste matter from any creamery, cheese factory or laundry, nor water in which milk cans, utensils, clothing, bedding, carpets, or harness have been washed or rinsed, or any polluted water or liquid of any kind shall be thrown, or discharged directly or indirectly into any reservoir or watercourse, nor

shall any such liquid or solid refuse or waste be thrown, discharged or allowed to escape or remain upon the surface of the ground or to percolate into or through the ground below the surface in any manner whereby the same may flow into any reservoir or watercourse within a distance of 100 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon.

9. No clothing, bedding, carpets, harnesses, vehicle, receptacles, utensils, nor anything that pollutes water shall be washed, rinsed, or placed in any reservoir or watercourse.

Bathing, Animals, Manure, Compost, Etc.

10. No person shall be allowed to bathe in any reservoir nor shall any animals or poultry be allowed to stand, wallow, wade or swim in any reservoir, nor be washed therein. The watering of animals or poultry in any reservoir of the public water supply of the city of Beacon is prohibited. No watering place shall be maintained in such a way as to pollute with muddy leachings or excretal matters any streams tributary to the public water supply of the city of Beacon.

11. No stable for cattle or horses, barnyard, hogyard, pigpen, poultry house or yard, hitching place or standing place for horses or other animals, manure pile or compost heap, shall be constructed, placed, maintained or allowed to remain with its nearest point less than 100 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon, and none of the above-named objects or sources of pollution shall be so constructed, placed, maintained, or allowed to remain where or in such a manner that the drainings, leachings or washings from the same may enter any such reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that proper purification has been secured unless the above drainings, leachings or washings shall have percolated over or through the soil in a scattered dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 100 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon.

12. No human excreta and no compost or other matter containing human excreta shall be thrown, placed or allowed to escape into any reservoir or watercourse, nor to be placed, piled or spread upon the surface of the ground at any point on the watershed tributary to the public water supply of the city of Beacon, nor shall such human excreta or compost or other matter containing human excreta be dug or buried in the soil at a less depth than 18 inches below the surface nor within a distance of 500 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon, and no manure or compost of any kind shall be placed, piled or spread upon the ground within a distance of 200 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon.

13. No decayed or fermented fruit or vegetables, cider mill wastes, roots, grain or other vegetable refuse of any kind shall be thrown, placed, discharged or allowed to escape or pass into any reservoir or watercourse, nor shall they be thrown, placed, piled, maintained or allowed to remain in such places that the drainings, leachings or washings therefrom may flow by open, blind or covered drains or channels of any kind into any reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that sufficient purification has been secured unless the above-mentioned drainings, leachings or washings shall have percolated over or through the soil in a scattered, dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 75 feet before entering any reservoir or watercourse tributary to the public water supply of the city of Beacon.

Dead Animals, Offal, Manufacturing Wastes, Etc.

14. No dead animals, bird, fish or any part thereof nor any offal or waste matter of any kind, shall be thrown, placed, discharged or allowed to escape or to pass into any reservoir or watercourse. Nor shall any such material or refuse be so located, placed, maintained or allowed to remain that the drainage, leachings or washings therefrom may reach any such reservoir or watercourse without having first percolated over or through the soil in a scattered, dissipated form and not concentrated in perceptible lines of drainage, for a distance of 200 feet from any reservoir or watercourse tributary to the public water supply of the city of Beacon.

Fishing, Boating and Ice Cutting

15. No boating of any kind or fishing from boats or through the ice, and no ice cutting or any trespassing whatever shall be allowed in or upon the waters or ice of the reservoirs.

Labor Camps

16. No temporary camp, tent, building or other structures for housing laborers engaged on construction work or for other purposes shall be located, placed or maintained within a distance of 500 feet from any reservoir or 100 feet from any watercourse tributary to the public water supply of the city of Beacon.

Cemeteries

17. No interment of a human body shall be made within a distance of 300 feet from any reservoir or 100 feet from any watercourse tributary to the public water supply of the city of Beacon.

Inspections

18. The board of public works of the city of Beacon shall make regular and thorough inspection of the reservoirs, streams and drainage areas tributary thereto for the purpose of ascertaining whether the above rules and regulations are being complied with, and it shall be the duty of said board of public works to cause copies of any rules and regulations violated to be served upon the persons violating the same, with notices of such violations; and if such persons served do not immediately comply with the rules and regulations it shall be the further duty of the board of public works to promptly notify the State Commissioner of Health of such violations. The board of public works shall report in writing annually on the first day of January the results of the regular inspections made during the preceding year, stating the number of inspections which have been made, the number of violations found, the number of notices served, and the general condition of the watershed at the time of the last inspection.

Penalty

19. In accordance with section 70 of chapter 45 of the Consolidated Laws (Public Health Law) the penalty for each and every violation of, or noncompliance with, any of these rules and regulations which relate to a permanent source or act of contamination, is hereby fixed at $100.

The foregoing rules and regulations for the protection from contamination of the public water supply of the city of Beacon are hereby duly made, ordained and established on this 15th day of November, 1921, pursuant to chapter 45 of the Consolidated Laws (Public Health Law) of the State of New York, as finally amended, by chapter 510 of the Laws of 1921.

Albany, N. Y.

M. NICOLL, JR.,
Deputy State Commissioner of Health.

BROCTON

The rules and regulations hereinafter given, duly made and enacted in accordance with the provisions of sections 70, 71 and 73 of chapter 45 of the Consolidated Laws (Public Health Law) as heretofore set forth shall apply to all natural and artificial reservoirs on Slippery Rock creek and to all watercourses tributary thereto or ultimately discharging into said reservoirs, these bodies of water being sources of the public water supply of the village of Brocton, Chautauqua county, N. Y. The term "reservoir" wherever used in these rules is intended to mean and refer to all storage and impounding reservoirs on Slippery Rock creek, which are tributary to or which serve as sources of this public water supply or to any additional reservoir which may be constructed or used for the purpose of this public water supply. The term "watercourse" wherever used in these rules is intended to mean and include every spring, pond (other than the artificial reservoirs and filter basins) stream, ditch, gutter or other channel of any kind the waters of which when running whether continuously or occasionally eventually flow or may flow into the public water supply of the village of Brocton.

Wherever a linear distance of a structure or object from a reservoir or from a watercourse is mentioned in these rules it is intended to mean the shortest horizontal distance from the nearest point of the structure or object to the highwater mark of a reservoir or to the edge, margin or precipitous bank forming the ordinary highwater mark of such watercourse.

Privies Adjacent to Any Reservoir or Watercourse

1. No privy, privy vault, pit, cesspool or any other receptacle of any kind used for either the temporary storage or the permanent deposit of human excreta shall be constructed, placed, maintained or allowed to remain within 200 feet of any reservoir or within 75 feet of any watercourse tributary to the public water supply of Brocton.

2. No privy, privy vault, pit, cesspool or any other receptacle used for the permanent deposit of human excreta shall be constructed, located, placed, maintained or allowed to remain within 300 feet of any reservoir or within 100 feet of any watercourse tributary to the public water supply of Brocton.

3. No cesspool, pit or other receptacle of any kind used for the deposit or storage of human excreta or sewage shall be constructed, located, maintained or allowed to remain between the limiting distances prescribed by Rule 1 and the limiting distances prescribed by Rule 2 unless said cesspool, pit or other receptacle is so arranged and equipped that the said excreta or sewage are at once removed by pump or other satisfactory means through watertight pipes or conduits to some proper place of ultimate disposal, as hereinafter provided, or unless suitable removable vessels or receptacles for the temporary storage of said human excreta or sewage are provided and at all times maintained in an absolutely watertight condition and in such manner as to permit of convenient removal of said excreta or sewage to some place of ultimate disposal as hereinafter set forth.

4. The excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall be removed and the receptacles thoroughly cleaned and deodorized as often as may be found necessary to maintain the privy in proper sanitary condition and to effectually prevent any overflow upon the soil or upon the foundation or floor of the privy. In effecting this removal the utmost care shall be exercised that none of the contents be allowed to escape while being transferred from the privy to the place of disposal hereinafter specified, and that the contents while being transferred from the privy to the place of disposal, shall be thoroughly covered and that the least possible annoyance and inconvenience be caused to occupants of the premises and the adjacent premises.

5. Unless otherwise specially ordered or permitted by the State Commissioner of Health, the excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall, when removed be disposed of by burying in

trenches or pits at a depth of not less than 18 inches below the surface and at a distance not less than 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Brocton, and in such a manner and at such a place as to effectively prevent its being washed over the surface of, or through the ground, in an imperfectly purified condition into any reservoir or watercourse tributary to the public water supply of the village of Brocton.

6. Whenever, owing to the character of the soil or of the surface of the ground, or to the height or flow of subsoil or surface water, or to other special local conditions it is considered by the State Commissioner of Health that excremental matter from any privy or aforesaid receptacle, or from any trench or place of disposal, or the garbage or wastes from any dump, may be washed over the surface or through the soil in an imperfectly purified condition into any reservoir or watercourse, then the said privy or receptacle for excreta, or the trench or place of disposal, or the said garbage or waste dump, shall be removed to such greater distance or to such place as shall be considered safe and proper by the State Commissioner of Health.

Sewage, House Slops, Sink Wastes, Etc.

7. No house slops, bath water, sewage or other excretal matter from any water closet, privy, cesspool or other source, except the purified effluent from a properly constructed sewage disposal plant approved by the State Commissioner of Health, as required by law, shall be' thrown, placed, led, conducted, discharged or allowed to escape or flow in any manner either directly or indirectly into any reservoir or any watercourse tributary to the public water supply of the village of Brocton, nor shall any such matters be thrown, placed, led, discharged or allowed to escape or flow on the surface of the ground, or into the ground beneath the surface except into watertight receptacles the contents of which are to be removed, as provided by Rule 4 within 300 feet of any reservoir or within 100 feet of any watercourse tributary to the public water supply of the village of Brockton.

8. No garbage, putrescible matter, kitchen or sink wastes, refuse or waste matter from any creamery, cheese factory or laundry, nor water in which milk cans, utensils, clothing, bedding, carpets, or harness have been washed or rinsed, nor any polluted water or liquid of any kind shall be thrown. or discharged directly or indirectly into any reservoir or watercourse, nor shall any such liquid or solid refuse or waste be thrown, discharged or allowed to escape, flow, or remain upon the surface of the ground or to percolate into or through the ground below the surface in any manner whereby the same may flow or percolate into any reservoir or watercourse within a distance of 200 feet from any reservoir or within 75 feet from any watercourse tributary to the public water supply of the village of Brocton.

9. No clothing, bedding, carpets, harnesses, vehicle, receptacles, utensils, nor anything that pollutes water, shall be washed, rinsed, or placed in any reservoir or watercourse tributary to the public water supply of the village of Brocton.

Bathing, Animals, Manure, Compost, Etc.

10. No person shall bathe nor shall any animal be allowed to stand, wallow, wade or swim, nor be washed, nor watered in any reservoir of the public water supply of the village of Brocton. No watering place shall be maintained in such a way as to pollute with muddy leachings or excretal matters any streams tributary to the public water supply of the village of Brocton.

11. No stable for cattle or horses, barnyards, hogyard, pigpen, poultry house or yard, hitching place or standing place for horses or other animals, manure pile or compost heap, shall be constructed, placed, maintained or allowed to remain with its nearest point less than 300 feet from any reservoir or within 75 feet of any watercourse tributary to the public water supply of the village of Brocton, and none of the above named objects or sources of pollution shall be so constructed, placed, maintained or allowed to remain where or in such a manner that the drainings, leachings or washings from

the same may enter any such reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that proper purification has been secured unless the above drainings, leachings or washings shall have percolated over or through the soil in a scattered dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 300 feet to any reservoir or 50 feet to any watercourse tributary to the public water supply of the village of Brocton.

12. No human excreta and no compost or other matter containing human excreta shall be thrown, placed or allowed to escape into any reservoir or watercourse, nor to be placed, piled or spread upon the surface of the ground at any point on the watershed tributary to the public water supply of the village of Brocton, nor shall any such human excreta or compost or other matter containing human excreta be dug or buried in the soil at a less depth than 18 inches below the surface nor within a distance of 300 feet from any reservoir nor within 150 feet of any watercourse tributary to the public water supply of the village of Brocton, and no manure or compost of any kind shall be placed, piled, or spread upon the ground within a distance of 300 feet from any reservoir or within 50 feet from any watercourse tributary to the public water supply of Brocton.

13. No decayed or fermented fruit or vegetables, cider mill wastes, roots, grain or other vegetable refuse of any kind shall be thrown, placed, discharged or allowed to escape or pass into any reservoir or watercourse, nor shall they be thrown, placed, piled, maintained or allowed to remain in such places that the drainage, leachings or washings therefrom may flow by open, blind or covered drains or channels of any kind into any reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that sufficient purification has been secured unless the above mentioned drainings, leachings, or washings shall have percolated over or through the soil in a scattered, dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 200 feet before entering any reservoir or 50 feet before entering any watercourse tributary to the public water supply of the village of Brocton.

Dead Animals, Offal, Manufacturing Wastes, Etc.

14. No dead animals, bird, fish or any part thereof nor any offal or waste matter of any kind, shall be thrown, placed, discharged or allowed to escape or to pass into any reservoir or watercourse. Nor shall any such material or refuse be so located, placed, maintained or allowed to remain that the drainage, leachings, or washings therefrom may reach any such reservoir or watercourse without having first percolated over or through the soil in a scattered dissipated form and not concentrated in perceptible lines of drainage, for a distance of 300 feet from any reservoir or 100 feet from any watercourse tributary to the public water supply of Brocton.

Fishing, Boating and Ice Cutting

15. No boating of any kind, or fishing from boats, or through the ice and no ice cutting or any trespassing whatever shall be allowed in or upon the waters or ice of the reservoir.

Labor Camps

16. No temporary camp, tent, building or other structures for housing laborers engaged on construction work or for other purposes shall be located, placed or maintained within a distance of 500 feet from any reservoir or 300 feet from any watercourse tributary to the public water supply of Brocton.

Cemeteries

17. No interment of a human body shall be made within a distance of 500 feet from any reservoir or 250 feet from any watercourse tributary to the public water supply of Brocton.

Inspections

18. The board of trustees of the village of Brocton or such other board, body, or person as may be charged with the maintenance of the public water supply of the village shall make or cause to be made regular and thorough inspections of the reservoirs, streams and drainage areas tributary thereto for the purpose of ascertaining whether the above rules and regulations are being complied with, and it shall be the duty of said board to cause copies of any rules and regulations violated to be served upon the persons violating the same with notices of such violations; and if such persons served do not immediately comply with the rules and regulations it shall be the further duty of the board of water commissioners to promptly notify the State Commissioner of Health of such violations. The board shall report in writing annually on the first day of January, the results of the regular inspections made during the preceding year stating the number of inspections which have been made, the number of violations found, the number of notices served, and the general condition of the watershed at the time of the last inspection.

Penalty

19. In accordance with section 70 of chapter 45 of the Consolidated Laws (Public Health Law), the penalty for each and every violation of or noncompliance with any of these rules and regulations which relate to a permanent source or act of contamination, is hereby fixed at $100.

The foregoing rules and regulations for the protection from contamination of the public water supply of Brocton are hereby duly made, ordained and established on this 23rd day of April, 1921, pursuant to chapter 45 of the Consolidated Laws (Public Health Law), of the State of New York, as finally amended by chapter 665 of the Laws of 1915.

M. NICOLL, JR.
ALBANY, N. Y. *Deputy Commissioner of Health*

CANTON

The rules and regulations hereinafter given, duly made and enacted in accordance with the provisions of sections 70, 71 and 73 of chapter 45 of the Consolidated Laws (Public Health Law), as heretofore set forth, shall apply to all natural and artificial reservoirs of the Barringer, Collar, Barrett, O'Brien, Allen, Matthews and Dinsdale springs and to all watercourses tributary thereto or ultimately discharging into said reservoirs, these bodies of water being sources of the public water supply of the village of Canton, St. Lawrence county, New York. The term "reservoir" wherever used in these rules is intended to mean and refers to all impounding and storage reservoirs used for the collection or storage of the flow from the above named springs which are tributary to or which serve as sources of this public water supply or to any additional reservoir which may be constructed or used for the purpose of this public water supply. The term "watercourse" wherever used in these rules is intended to mean and include every spring, pond (other than the artificial reservoirs and filter basins) stream, ditch, gutter or channel of any kind, the waters of which, when running whether continuously or occasionally, eventually flow or may flow into the public water supply of Canton.

Wherever a linear distance of a structure or object from a reservoir or from a watercourse is mentioned in these rules, it is intended to mean the shortest horizontal distance from the nearest point of the structure or object to the high-water mark of a reservoir or to the edge, margin or precipitous bank forming the ordinary high-water mark of such watercourse.

Privies Adjacent to any Reservoir or Watercourse

1. No privy, privy vault, pit, cesspool or receptacle of any kind used for either the temporary storage or the permanent deposit of human excreta shall be constructed, placed, maintained or allowed to remain within 200 feet of any reservoir or within 100 feet of any watercourse tributary to the public water supply of the village of Canton, N. Y.

2. No privy, privy vault, pit, cesspool or other receptacle used for the permanent deposit of human excreta shall be constructed, located, placed, maintained or allowed to remain within 300 feet of any reservoir or within 200 feet of any watercourse tributary to the public water supply of the village of Canton, N. Y.

3. No cesspool, pit or other receptacle used for the temporary storage of human excreta or sewage shall be constructed, located, maintained or allowed to remain between the limiting distances prescribed by Rule 1 and the limiting distances prescribed by Rule 2 unless said cesspool, pit or other receptacle is watertight and so arranged and equipped that the said excreta or sewage will not overflow and is at once removed by pump or other satisfactory means through watertight pipes or conduits to some proper place of ultimate disposal, as hereinafter provided; except that suitable removable vessels or receptacles for the temporary storage of said human excreta or sewage may be provided and maintained between the said limiting distances if at all times maintained in an absolutely watertight condition and in such manner as to permit of convenient removal of said excreta or sewage to some place of ultimate disposal as hereinafter set forth.

4. The excreta collected in the aforesaid removable vessels or receptacles permitted under Rule 3 shall be removed and vessels or receptacles thoroughly cleaned and deodorized as often as may be found necessary in order to maintain them or the privy or place in which they are kept in proper sanitary condition and to effectually prevent any overflow upon the soil or upon the foundation or floor of the privy or other place. In effecting this removal the utmost care shall be exercised that none of the contents be allowed to escape while being transferred from the privy or place of temporary storage to the place of final disposal hereinafter specified, and that the contents while being transferred shall be effectively covered and that the least possible annoyance and inconvenience be caused to occupants of the premises and the adjacent premises.

5. Unless otherwise specially ordered or permitted by the State Department of Health, the excreta collected in the aforesaid removable receptacle permitted under Rule 3 shall, when removed be disposed of by burying in trenches or pits at a depth of not less than 18 inches below the surface and at a distance not less than 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Canton.

6. Whenever, owing to the character of the soil or of the surface of the ground, or owing to the height or flow of subsoil or surface water, or other special local conditions it is considered by the State Commissioner of Health that excremental matter from any privy or aforesaid receptacles or from any trench or place of disposal, or the garbage or wastes from any dump, may be washed over the surface or through the soil in an imperfectly purified condition into any reservoir or watercourse, then the said privy or receptacle for excreta, or the trench or place of disposal, or the said garbage or waste dump, shall, after due notice to the owner thereof, be removed to such greater distance or to such place as shall be considered safe and proper by the State Commissioner of Health.

Sewage, House Slops, Sink Wastes, Etc.

7. No house slops, bath water, sewage or other excretal matter from any water closet, privy, cesspool or other source, except the purified effluent from a properly constructed sewage disposal plant approved by the State Department of Health, as required by law, shall be thrown, placed, led conducted, discharged or allowed to escape or flow in any manner either directly or indirectly into any reservoir or any watercourse tributary to the public water

supply of Canton, nor shall any such matters be thrown, placed, led, discharged or allowed to escape on or beneath the surface of the ground, except into watertight receptacles, the contents of which are to be removed as provided by Rule 4, within 300 feet of any reservoir or within 200 feet of any watercourse tributary to the public water supply of the village of Canton.

8. No garbage, putrescible matter, kitchen or sink wastes, refuse or waste matter from any creamery, cheese factory or laundry, water in which milk cans, utensils, clothing, bedding, carpets or harness have been washed or rinsed, nor any polluted water or liquid of any kind shall be thrown or discharged directly or indirectly into any reservoir or watercourse; nor shall any such liquid or solid refuse or waste be thrown, discharged or allowed to escape or remain upon the surface of the ground, or be allowed to escape or percolate into or through the ground below the surface within a distance of 200 feet from any reservoir or within 100 feet from any watercourse tributary to the public water supply of Canton.

9. No clothing, bedding, carpets, harnesses, vehicle, receptacles, utensils, nor anything that pollutes water, shall be washed, rinsed or placed in any reservoir or watercourse.

Bathing, Animals, Manure, Compost, Etc.

10. No person shall be allowed to bathe in any reservoir or tributary thereof, nor shall any animals or poultry be allowed to stand, wallow, wade or swim in any reservoir or tributary thereof nor be washed therein. No animals or poultry shall be watered in any reservoir of the public water supply of the village of Canton. No watering place of any kind shall be maintained in such a way as to pollute with muddy leachings or excretal matters any streams tributary to the public water supply of the village of Canton.

11. No stable for cattle or horses, barnyard, hogyard, pigpen, poultry house or yard, hitching place or standing place for horses or other animals, manure pile or compost heap, shall be constructed, placed, maintained or allowed to remain with its nearest point less than 300 feet from any reservoir or within 200 feet of any watercourse tributary to the public water supply of Canton, and none of the above named objects or sources of pollution shall be so constructed, placed, maintained or allowed to remain where or in such a manner that the drainage, leachings or washings from the same may enter any such reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that proper purification has been secured unless the above drainings, leachings or washings shall have percolated over or through the soil in a scattered dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 300 feet from any reservoir or 200 feet from any watercourse tributary to the public water supply of the village of Canton.

12. No human excreta and no compost or other matter containing human excreta shall be thrown, placed or allowed to escape into any reservoir or watercourse, nor to be placed, piled or spread upon the surface of the ground at any point on the watershed tributary to the public water supply of the village of Canton, nor shall such human excreta or compost or other matter containing human excreta be dug or buried in the soil at a less depth than 18 inches below the surface nor within a distance of 500 feet from any reservoir nor within 300 feet of any watercourse tributary to the public water supply of the village of Canton, and no manure or compost of any kind shall be placed, piled or spread upon the ground within a distance of 200 feet from any reservoir or within 100 feet from any watercourse or ditch tributary to the public water supply of the village of Canton.

13. No decayed or fermented fruit or vegetables, cider-mill wastes, roots, grain or other vegetable refuse of any kind shall be thrown, placed, discharged or allowed to escape or pass into any reservoir or watercourse, nor shall they be thrown, placed, piled, maintained or allowed to remain in such

places that the drainage, leachings or washings therefrom may flow by open, blind or covered drains or channels of any kind into any reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that sufficient purification has been secured unless the above mentioned drainings, leachings or washings shall have percolated over or through the soil in a scattered, dissipated form and not concentrated in perceptible lines of drainage for a distance of not less than 100 feet before entering any reservoir or watercourse tributary to the public water supply of the village of Canton.

Dead Animals, Offal, Manufacturing Wastes, Etc.

14. No dead animals, bird, fish or any part thereof nor any offal or waste matter of any kind, shall be thrown, placed, discharged or allowed to escape or to pass into any reservoir or watercourse. Nor shall any such material or refuse be so located, placed, maintained or allowed to remain that the drainage, leachings or washings therefrom may reach any such reservoir or watercourse without having first percolated over or through the soil in a scattered, dissipated form and not concentrated in perceptible lines of drainage, for a distance of 300 feet from any reservoir or 200 feet from any watercourse tributary to the public water supply of the village of Canton.

Fishing Boating and Ice Cutting

15. No boating or fishing of any kind, and no ice cutting or trespassing whatever shall be allowed in or upon the waters or ice of the reservoir.

Labor Camps

16. No temporary camp, tent, building or other structures for housing laborers engaged on construction work or for other purposes shall be located, placed or maintained within a distance of 500 feet from any reservoir or 300 feet from any watercourse tributary to the public water supply of the village of Canton.

Cemeteries

17. No interment of a human body shall be made within a distance of 500 feet from any reservoir or 300 feet from any watercourse tributary to the public water supply of the village of Canton.

Inspections

18. The board of water commissioners of the village of Canton shall make regular and thorough inspections of the reservoirs, streams and drainage areas tributary thereto for the purpose of ascertaining whether the above rules and regulations are being complied with, and it shall be the duty of said board of water commissioners to cause copies of any rules and regulations violated to be served upon the persons violating the same with notices of such violations; and if such persons served do not immediately comply with the rules and regulations it shall be the further duty of the board of water commissioners to promptly notify the State Commissioner of Health of such violations. The board of water commissioners shall report in writing annually, on the first day of January, the results of the regular inspections made during the preceding year, stating the number of inspections which have been made, the number of violations found, the number of notices served, and the general condition of the watershed at the time of the last inspection.

Penalty

19. In accordance with section 70 of chapter 45 of the Consolidated Laws (Public Health Law) the penalty for each and every violation of, or noncompliance with, any of these rules and regulations which relate to a permanent source or act of contamination, is hereby fixed at $100.

The foregoing rules and regulations for the protection from contamination of the public water supply of Canton are hereby duly made, ordained and established on this 11th day of April, 1921, pursuant to chapter 45 of the Consolidated Laws (Public Health Law) of the State of New York, as finally amended by chapter 665 of the Laws of 1915.

M. NICOLL, JR.,
Albany, N. Y. *Deputy Commissioner of Health.*

NEWARK

The rules and regulations hereinafter given, duly made and enacted in accordance with the provisions of sections 70, 71 and 73 of chapter 45 of the Consolidated Laws (Public Health Law), as heretofore set forth, shall apply to all natural and artificial reservoirs on Case creek and to all watercourses tributary thereto or ultimately discharging into said reservoirs, these bodies of water being sources of the public water supply of the village of Newark, Wayne county, N. Y. The term "reservoir," wherever used in these rules, is intended to mean and refer to all storage and impounding reservoirs on Case creek which are tributary to or which serve as sources of this public water supply or to any additional reservoir which may be constructed or used for the purpose of this public water supply. The term "watercourse," wherever used in these rules, is intended to mean and include every spring, pond (other than the artificial reservoirs and filter basins), stream, ditch, gutter or other channel of any kind, the waters of which when running, whether continuously or occasionally, eventually flow or may flow into the public water supply of the village of Newark.

Wherever a linear distance of a structure or object from a reservoir or from a watercourse is mentioned in these rules it is intended to mean the shortest horizontal distance from the nearest point of the structure or object to the highwater mark of a reservoir or to the edge, margin or precipitous bank forming the ordinary highwater mark of such watercourse.

Privies Adjacent to any Reservoir or Watercourse.

1. No privy, privy vault, pit, cesspool or any other receptacle of any kind used for either the temporary storage or the permanent deposit of human excreta shall be constructed, placed, maintained or allowed to remain within 200 feet of any reservoir or within 75 feet of any watercourse tributary to the public water supply of the village of Newark.

2. No privy, privy vault, pit, cesspool or any other receptacle used for the permanent deposit of human excreta shall be constructed, located, placed, maintained or allowed to remain within 300 feet of any reservoir or within 150 feet of any watercourse tributary to the public water supply of the village of Newark.

3. No cesspool pit or other receptacle of any kind used for the deposit or storage of human excreta or sewage shall be constructed, located, maintained or allowed to remain between the limiting distances prescribed by Rule 1 and the limiting distances prescribed by Rule 2, unless said cesspool, pit or other receptacle is so arranged and equipped that the said excreta or sewage are at once removed by pump or other satisfactory means through watertight pipes or conduits to some proper place of ultimate disposal, as hereinafter provided, or unless suitable removable vessels or receptacles for the temporary storage of said human excreta or sewage are provided and at all times maintained in an absolutely watertight condition and in such manner as to permit of convenient removal of said excreta or sewage to some place of ultimate disposal as hereinafter set forth.

4. The excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall be removed and the receptacles thoroughly cleaned and deodorized as often as may be found necessary to maintain

the privy in proper sanitary condition and to effectually prevent any overflow upon the soil or upon the foundation or floor of the privy. In effecting this removal the utmost care shall be exercised that none of the contents be allowed to escape while being transferred from the privy to the place of disposal hereinafter specified, and that the contents, while being transferred from the privy to the place of disposal, shall be thoroughly covered and that the least possible annoyance and inconvenience be caused to occupants of the premises and the adjacent premises.

5. Unless otherwise specially ordered or permitted by the State Commissioner of Health, the excreta collected in the aforesaid removable receptacles permitted under Rule 3 shall, when removed, be disposed of by burying in trenches or pits at a depth of not less than 18 inches below the surface and at a distance of not less than 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Newark and in such a manner and at such a place as to effectually prevent its being washed over the surface of or through the ground in an imperfectly purified condition into any reservoir or watercourse tributary to the public water supply of the village of Newark.

6. Whenever, owing to the character of the soil or of the surface of the ground, or to the height or flow of subsoil or surface water, or to other special local conditions it is considered by the State Commissioner of Health that excremental matter from any privy or aforesaid receptacle, or from any trench or place of disposal, or the garbage or wastes from any dump, may be washed over the surface or through the soil in an imperfectly purified condition into any reservoir or watercourse, then the said privy or receptacle for excreta, or the trench or place of disposal, or the said garbage or waste dump, shall, after due notice to the owner thereof, be removed to such greater distance or to such place as shall be considered safe and proper by the State Commissioner of Health.

Sewage, House Slops, Sink Wastes, Etc.

7. No house slops, bath water, sewage or other excretal matter from any water closet, privy, cesspool or other source, except the purified effluent from a properly constructed sewage disposal plant approved by the State Commissioner of Health, as required by law, shall be thrown, placed, led, conducted, discharged or allowed to escape or flow in any manner either directly or indirectly into any reservoir or any watercourse tributary to the public water supply of the village of Newark, nor shall any such matters be thrown, placed, led, discharged or allowed to escape or flow on the surface of the ground or into the ground beneath the surface, except into watertight receptacles, the contents of which are to be removed, as provided by Rule 4, within 300 feet of any reservoir or within 150 feet of any watercourse tributary to the public water supply of the village of Newark.

8. No garbage, putrescible matter, kitchen or sink wastes, refuse or waste matter from any creamery, cheese factory or laundry, nor water in which milk cans, utensils, clothing, bedding, carpets or harness have been washed or rinsed, nor any polluted water or liquid of any kind shall be thrown, or discharged directly or indirectly into any reservoir or watercourse, nor shall any such liquid or solid refuse or waste be thrown, discharged or allowed to escape, flow or remain upon the surface of the ground or to percolate into or through the ground below the surface in any manner whereby the same may flow or percolate into any reservoir or watercourse within a distance of 200 feet from any reservoir or within 75 feet from any watercourse tributary to the public water supply of the village of Newark.

9. No clothing, bedding, carpets, harness, vehicle, receptacles, utensils, nor anything that pollutes water shall be washed, rinsed or placed in any reservoir or watercourse tributary to the public water supply of the village of Newark.

Bathing, Animals, Manure, Compost, Etc.

10. No person shall bathe nor shall any animal be allowed to stand, wallow wade or swim, nor be washed or watered in any reservoir of the public water supply of the village of Newark. No watering place shall be maintained in such a way as to pollute with muddy leachings or excretal matters any streams tributary to the public water supply of the village of Newark.

11. No stable for cattle or horses, barnyards, hogyard, pigpen, poultry house or yard, hitching place or standing place for horses or other animals, manure pile or compost heap, shall be constructed, placed, maintained or allowed to remain with its nearest point less than 300 feet from any reservoir or within 75 feet of any watercourse tributary to the public water supply of the village of Newark, and none of the above-named objects or sources of pollution shall be so constructed, placed, maintained or allowed to remain where or in such a manner that the drainings, leachings or washings from the same may enter any such reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that proper purification has been secured unless the above drainings, leachings or washings shall have percolated over or through the soil in a scattered, dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 300 feet to any reservoir or 75 feet to any watercourse tributary to the public water supply of the village of Newark.

12. No human excreta and no compost or other matter containing human excreta shall be thrown, placed or allowed to escape into any reservoir or watercourse, nor to be placed, piled or spread upon the surface of the ground at any point on the watershed tributary to the public water supply of the village of Newark, nor shall such human excreta or compost or other matter containing human excreta be dug or buried in the soil at a less depth than 18 inches below the surface nor within a distance of 300 feet from any reservoir nor within 150 feet of any watercourse tributary to the public water supply of the village of Newark, and no manure or compost of any kind shall be placed, piled or spread upon the ground within a distance of 300 feet from any reservoir or within 150 feet from any watercourse tributary to the public water supply of the village of Newark.

13. No decayed or fermented fruit or vegetables, cider-mill wastes, roots, grain or other vegetable refuse of any kind shall be thrown, placed, discharged or allowed to escape or pass into any reservoir or watercourse, nor shall they be thrown, placed, piled, maintained or allowed to remain in such places that the drainage, leachings or washings therefrom may flow by open, blind or covered drains or channels of any kind into any reservoir or watercourse without first having passed over or through such an extent of soil as to have been properly purified, and in no case shall it be deemed that sufficient purification has been secured unless the above mentioned drainings, leachings or washings shall have percolated over or through the soil in a scattered, dissipated form, and not concentrated in perceptible lines of drainage for a distance of not less than 200 feet before entering any reservoir or 50 feet before entering any watercourse tributary to the public water supply of the village of Newark.

Dead Animals, Offal, Manufacturing Wastes, Etc.

14. No dead animals, bird, fish or any part thereof nor any offal or waste matter of any kind, shall be thrown, placed, discharged or allowed to escape or to pass into any reservoir or watercourse. Nor shall any such material or refuse be so located, placed, maintained or allowed to remain that the drainage, leachings or washings therefrom may reach any such reservoir or watercourse without having first percolated over or through the soil in a scattered, dissipated form and not concentrated in perceptible lines of drainage, for a distance of 300 feet from any reservoir or 75 feet from any watercourse tributary to the public water supply of the village of Newark.

Fishing, Boating and Ice Cutting

15. No boating of any kind, or fishing from boats, or through the ice, and no ice cutting or any trespassing whatever shall be allowed in or upon the waters or ice of the reservoir.

Labor Camps

16. No temporary camp, tent, building or other structures for housing laborers engaged on construction work or for other purposes shall be located, placed or maintained within a distance of 500 feet from any reservoir or 300 feet from any watercourse tributary to the public water supply of the village of Newark.

Cemeteries

17. No interment of a human body shall be made within a distance of 500 feet from any reservoir or 250 feet from any watercourse tributary to the public water supply of the village of Newark.

Inspection

18. The municipal board of the village of Newark or such other board, body or person as may be charged with the maintenance of the public water supply of the village, shall make or cause to be made regular and thorough inspections of the reservoirs, streams and drainage areas tributary thereto for the purpose of ascertaining whether the above rules and regulations are being complied with, and it shall be the duty of said board to cause copies of any rules and regulations violated to be served upon the persons violating the same with notices of such violations; and if such persons served do not immediately comply with the rules and regulations it shall be the further duty of the board of water commissioners to promptly notify the State Commissioner of Health of such violations. The board shall report in writing annually on the first day of January the results of the regular inspections made during the preceding year, stating the number of inspections which have been made, the number of violations found, the number of notices served, and the general condition of the watershed at the time of the last inspection.

Penalty

19. In accordance with section 70 of Chapter 45 of the Consolidated Laws (Public Health Law), the penalty for each and every violation of or noncompliance with any of these rules and regulations which relate to a permanent source or act of contamination, is hereby fixed at $100.

The foregoing rules and regulations for the protection from contamination of the public water supply of the village of Newark are hereby duly made, ordained and established on this thirteenth day of June, 1921, pursuant to chapter 45 of the Consolidated Laws (Public Health Law) of the State of New York, as finally amended by chapter 665 of the Laws of 1915.

M. NICOLL, JR.
ALBANY, N. Y. *Deputy Commissioner of Health*

NUNDA

The rules and regulations hereinafter given, duly made and enacted in accordance with the provisions of sections 70, 71 and 73 of Chapter 45 of the Consolidated Laws (Public Health Law), as heretofore set forth, shall apply to all springs, natural and artificial reservoirs and to all watercourses tributary to the public water supply of the village of Nunda, Livingston county, N. Y. The term "reservoir" wherever used is intended to mean and refer to the impounding and storage reservoirs used for the collection or storage of the flow from the Bradley and Seager springs or other watercourses tributary to the public water supply of the village of Nunda or to any other additional reservoir which may be constructed or used for the purpose of this public water supply. The term " watercourse " wherever used in these rules is intended to mean and include every spring, pond, stream, ditch, gutter or channel of any kind, the waters of which when running, whether continuously or occasionally, eventually flow or may flow into the public water supply of the village of Nunda.

Wherever a linear distance of a structure or object from a reservoir or from a watercourse is mentioned in these rules it is intended to mean the shortest horizontal distance from the nearest point of the structure or object to the high-water mark of a reservoir or to the edge, margin or precipitous bank forming the ordinary high-water mark of such watercourse.

Privies Adjacent to Any Reservoir or Watercourse

1. No privy, privy vault. pit, cesspool or receptacle of any kind used for either the temporary storage or the permanent deposit of human excreta shall be constructed, placed, maintained or allowed to remain within 300 feet of any reservoir or watercourse tributary directly or indirectly to the public water supply of the village of Nunda, N. Y.

Sewage, House Slops, Sink Wastes, Etc.

2. No house slops, bath water, sewage or other excretal matter from any water closet, privy, cesspool or other sources, shall be thrown, placed, led, conducted, discharged or allowed to escape or flow in any manner either directly or indirectly into any reservoir or any watercourse tributary to the public water supply of the village of Nunda, nor shall any such matters be thrown, placed, led, discharged or allowed to escape on or beneath the surface of the ground within 300 feet of any reservoir or watercourse tributary directly or indirectly to the public water supply of the village of Nunda.

3. No garage, putrescible matter, kitchen or sink wastes, refuse or waste matter from any creamery, cheese factory or laundry, water in which milk cans, utensils, clothing, bedding, carpets or harness have been washed or rinsed, nor any polluted water or liquid of any kind shall be thrown or discharged directly or indirectly into any reservoir or watercourse, nor shall any such liquid or solid refuse or waste be thrown, discharged or allowed to escape or remain upon the surface of the ground, or be allowed to escape or percolate into, or through the ground below the surface within a distance of 300 feet from any reservoir or watercourse tributary directly or indirectly to the public water supply of the village of Nunda.

4. No clothing, bedding, carpets, harnesses, vehicles, receptacles, utensils, nor anything that pollutes water, shall be washed, rinsed or placed in any reservoir or watercourse, tributary directly or indirectly to the water supply of the village of Nunda.

Bathing, Animals, Manure, Compost, Etc.

5. No person shall be allowed to bathe in any reservoir or tributary thereof nor shall any animals or poultry be allowed to stand, wallow, wade or swim in any reservoir or tributary thereof nor be washed therein. No animals or poultry shall be watered in any reservoir of the public water supply of the village of Nunda. No watering place of any kind shall be maintained in such a way as to pollute with muddy leachings or excretal matters any streams tributary to the public water supply of the village of Nunda.

6. No stable for cattle or horses, barnyard, hogyard, pigpen, poultry house or yard, hitching place or standing place for horses or other animals, manure pile or compost heap, shall be constructed, placed, maintained or allowed to remain with its nearest point less than 300 feet from any reservoir or watercourse tributary to the public water supply of Nunda.

7. No human excreta and no compost or other matter containing human excreta shall be thrown, placed or allowed to escape into any reservoir or watercourse, nor to be placed, piled or spread upon the surface of the ground

at any point on the watershed tributary to the public water supply of the village of Nunda, nor shall such human excreta or compost or other matter containing human excreta be dug or buried in the soil at a less depth than 18 inches below the surface nor within a distance of 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Nunda and no manure or compost of any kind shall be placed, piled or spread upon the ground within a distance of 200 feet from any reservoir or watercourse or ditch tributary to the public water supply of the village of Nunda.

8. No decayed or fermented fruit or vegetables, cider mill wastes, roots, grain or other vegetable refuse of any kind shall be thrown, placed, discharged or allowed to escape or pass into any reservoir or watercourse, nor shall they be thrown, placed, piled, maintained or allowed to remain in such places that the drainage, leachings or washings therefrom may flow by open, blind or covered drains or channels of any kind into any reservoir or watercourse tributary to the water supply of the village of Nunda.

Dead Animals, Offal, Manufacturing Wastes, Etc.

9. No dead animals, bird, fish or any part thereof nor any offal or waste matter of any kind, shall be thrown, placed, discharged or allowed to escape or to pass into any reservoir or watercourse. Nor shall any such material or refuse be so located, placed, maintained or allowed to remain that the drainage, leachings or washings therefrom may reach any such reservoir or watercourse without having first percolated over or through the soil in a scattered, dissipated form and not concentrated in perceptible lines of drainage, for a distance of 300 feet from any reservoir or watercourse tributary to the public water supply of the village of Nunda.

Fishing, Boating and Ice Cutting

10. No boating or fishing of any kind, and no ice cutting or trespassing whatever shall be allowed in or upon the waters or ice of the reservoir.

Labor Camps

11. No temporary camp, tent, building or other structure for housing laborers engaged on construction work or for other purposes shall be located, placed or maintained within a distance of 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Nunda.

Cemeteries

12. No interment of a human body shall be made within a distance of 500 feet from any reservoir or watercourse tributary to the public water supply of the village of Nunda.

Inspections

13. The board of water commissioners of the village of Nunda shall make regular and thorough inspections of the reservoirs, streams and drainage areas tributary thereto for the purpose of ascertaining whether the above rules and regulations are being complied with, and it shall be the duty of said board of water commissioners to cause copies of any rules and regulations violated to be served upon the persons violating the same with notices of such violations; and if such persons served do not immediately comply with the rules and regulations it shall be the further duty of the board of water commissioners to promptly notify the State Commissioner of Health of such violations. The Board of Water Commissioners shall report in writing annually on the first day of January, the results of the regular inspections made during the preceding year stating the number of inspections which have been made, the number of violations found, the number of notices served, and the general condition of the watershed at the time of the last inspection.

Penalty

14. In accordance with section 70 of chapter 45 of the Consolidated Laws (Public Health Law), the penalty for each and every violation of, or noncompliance with, any of these rules and regulations which relate to a permanent source or act of contamination, is hereby fixed at $100.

The foregoing rules and regulations for the protection from contamination of the public water supply of Nunda are hereby duly made, ordained and established on this 16th day of February, 1921, pursuant to chapter 45 of the Consolidated Laws (Public Health Law) of the State of New York, as finally amended, by chapter 665 of the Laws of 1915.

M. NICOLL, JR.
ALBANY, N. Y. *Deputy Commissioner of Health*

INSPECTIONS OF VIOLATIONS OF RULES FOR THE PROTECTION OF PUBLIC WATER SUPPLIES

During 1921 inspections of violations of rules and regulations were made and the necessary orders to the local boards of health issued in connection with the water supplies of the following municipalities: Cornell University, Kingston, New Rochelle and Stamford.

REPORTS FROM BOARDS OF WATER COMMISSIONERS AND WATER COMPANIES ON THE ENFORCEMENT OF RULES AND REGULATIONS FOR THE PROTECTION FROM CONTAMINATION OF PUBLIC WATER SUPPLIES

In December, 1921, a form letter was addressed to all the boards of water commissioners and water companies having charge of the public water supplies for which rules and regulations have been enacted by this department, calling their attention to the provisions of the Public Health Law requiring an annual report in writing on the first day of January of each year, giving the detailed results of the regular inspections of the sources, the steps taken to abate any violations found and a general description of the conditions existing on the watershed.

Such letters were transmitted to eighty-nine municipalities and replies were received from eighty-three of these municipalities. No word was received from the remaining six municipalities although letters were later sent to the officials calling their attention to this requirement.

INVESTIGATIONS OF PUBLIC WATER SUPPLIES

There are nearly 550 public water supplies in New York State, all of which have been investigated by this department in connection with the general policy of supervising the sanitary quality of the public water supplies throughout the state.

During the year 1921, investigations of some 204 public water supplies were made. The majority of these investigations were made either as a result of requests for advice or assistance from the local authorities or in connection with arrangement with the surgeon-general whereby this department agreed to furnish him yearly data as to the sanitary quality of the public water supplies used for drinking and culinary purposes by common carriers in interstate traffic.

These investigations include detailed field inspections of the watersheds and water purification plants, if any; the collection of samples of water for chemical and bacterial analyses; the collection of data regarding yield, water consumption, distribution systems, etc. Reports on these investigations are then prepared in the office. In these reports the water supplies are described, the results of analyses of the water discussed and interpreted and recommendations for improvements to the supplies are made.

AFTON

A reinspection of the public water supply of the village of Afton, Chenango county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on February 24, 1921. A previous inspection of this supply was made by this Division in the year 1916 and a report thereon published in the Annual Report of the Department for that year.

Afton is located about 25 miles northeast of Binghamton. The present population is estimated at 874 and all are served with the water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners, of which Mr. Martin Swart is president. There are two private sewers located in the village which discharge their contents in the Susquehanna river. Most of the residences are provided with privies, amounting to approximately 70 per cent, whereas the remaining 30 per cent are provided with cesspools and a few septic tanks.

The water supply is derived from springs located in Broome county over four miles south of the village. From the springs the water flows by gravity to the village. The springs are located in a small frame house and an area of about one acre around the springs is fenced to prevent trespassing. There are no houses above nor within one mile of the springs.

The results of the analyses of the samples of water collected from the village supply indicated that the water was of a fairly satisfactory sanitary quality at the time of the inspection.

It was recommended in a report dated March 12, 1921, that the authorities in charge of the water supply continue to maintain their careful supervision over the supply and post signs on the watershed to warn trespassers against wilful or accidental contamination of the supply.

ALEXANDRIA BAY

A reinspection of the public water supply of the village of Alexandria Bay was made by a representative of this Division on September 22, 1921. Previous inspections of this supply have been made in 1911, 1914, 1918 and 1919 and the reports thereon published in the Annual Reports of this Department.

Alexandria Bay has a population estimated at 1,850 in winter and 5,000, at times, in summer. It is located in the northwestern part of Jefferson county, on the St. Lawrence river in a central portion of the Thousand Island district between Clayton and Ogdensburg. Practically all of the population are served with the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners for which Mr. A. R. DeYoung is superintendent.

The water supply is obtained by pumping from the St. Lawrence river, through an intake pipe extending some 650 feet from shore in about 70 feet of water. The sewage from the village of Clayton, 14 miles above, is discharged directly into the river. The sewers of the houses on the numerous islands in the river above the intake and the toilet pipes from the river steamers also constitute sources of local pollution.

This Department has repeatedly recommended that measures be taken to purify the water supply and that the water be treated at all times with liquid chlorine in amounts sufficient to secure adequate sterilization. From the recent inspection it appears that the recommendations of this Department have not been acted upon.

In a report dated October 5, 1921, it was pointed out:

1. That while the need for carrying out the previous recommendations of this Department still remains, the authorities in charge of the water supply have carried out these recommendations only in part.
2. That raw St. Lawrence river water is not safe for domestic use at all times and its use is dangerous to the health of residents and visitors.

It was, therefore, recommended that the former recommendations of this Department be carried out and an apparatus for the adequate sterilization of water by chlorine be installed at once.

ALFRED

A reinspection of the public water supply of Alfred, Allegany county, was made by Mr. W. C. Emigh, an assistant engineer in this Department, on October 22, 1920. A previous investigation of the supply was made by this Department in 1916, a report of which is to be found on page 225 of the 38th Annual Report of the State Department of Health.

Alfred is an incorporated village having a population estimated to be about 700 persons. It is located in the eastern central part of Allegany county. Alfred University, which includes a State School of Agriculture, is located near the center of the village. A student population of about 350 increases the total population to approximately 1,050. There is no public sewer system in Alfred but in addition to numerous private cesspools serving 1 or 2 houses each, a private sewer and settling tank receive the sewage from the university and from 10 or more houses.

The water supply is owned by the village and is under the control of the board of trustees, of which Mr. Raymond Reynolds is president. Previous to 1917 the supply was obtained from two drilled wells about 190 feet and 180 feet in depth, respectively, and 2 springs, all of which are located about 2 miles west of the village. About 1916 a third well was drilled in the southwestern part of the village. The older wells are located about 100 feet apart and 50 feet from a public highway. The privy of the only house in the vicinity is about 400 feet distant from the nearer well.

The water from the deeper well is pumped by a 6-horsepower air cooled Gade natural gas engine, belt connected to a McEwan well jack. This pumping equipment is housed in a rough frame structure. No floor is provided within the building. The well tubing or casing extends about 1 foot above the surface of the ground. Although this tubing, which is 6 inches in diameter, is closed at the top, it is possible for oil to drip from the jack into the well. It appears that a possibility exists of pollution reaching the water supply by following the well casing to its extremity near the rock surface at a depth thought to be about 130 feet. The cylinder of the jack is about 12 feet above the bottom of the well. The jack used at present is badly worn and it was stated that an order had been placed for a new one.

The shallower of the wells is located in ground, the surface of which is slightly lower than that near the deeper well. In December, 1919, the pump house at this well was destroyed by fire. Such machinery as was not destroyed by the fire has been removed but the pump house has not been rebuilt. The pump house was provided with a concrete floor. It is stated that the village authorities are considering the construction of a new pump house in which would be installed a prime mover supplying the power for pumping the water from both wells. The pumps would then be operated by a line shaft or cable.

One spring is located on the side of a hill about 200 feet from the last described well. The village owns the land upon which this spring is located and extending up the hill a distance of about 40 feet. Above this line the land, which has a steep slope, is used for agricultural purposes. It appears that in the process of cultivation manure is drawn upon it and that opportunity for pollution from this source is thereby afforded.

The second spring is located nearby on a property line separating 2 pastures and at a distance of about ¼ mile from the wells. On the lower side the land is of a swampy character. There is no fence around the area in which the spring is located and cattle pastured in the field have access to its immediate vicinity. It could not be learned that the village owns any land near the spring.

Both springs are said to be in soil composed largely of clay. At times when the ground is saturated the entire water supply is turbid. There can be little doubt that the turbidity is due to water entering the mains from the springs and that surface wash may reach them readily.

The third well, which was placed in operation in 1917, is located on a steep hillside southwest of the village and at a distance of about 20 feet from the reservoir which receives the surplus water from the mains. It is 8 inches in diameter and 305 feet deep, all but 20 feet of which depth is in shale rock. Water is pumped from the well by air lift and flows by gravity into the reservoir. The pumping equipment consists of a 20-horsepower Lozier gas engine which drives an Ingersoll-Rand 8-inch by 8-inch compound compressor. The power house, which is a frame structure, is located on Reynolds street, convenient to the built-up portion of the village. A 1¼-inch air line extends to the well, and a 3-inch discharge line leads from the well to the nearby reservoir. The superintendent of waterworks stated that 60 pounds of air pressure is required to start pumping but that 30 pounds is then sufficient. The well is covered by a concrete slab and no means of access to the piping connections is provided.

Our engineer was informed that the village authorities have considered the drilling of additional wells near the reservoir and the abandonment of the wells and springs more distantly located with respect to the village. Such a plan presents the advantage of including only one power plant which may be located within the village whereas formerly 3 widely separated plants have been in use, two of which were at a distance of 2 miles from the center of the village and difficult of approach at times.

It was, therefore, recommended in a report dated January 29, 1921:

1. That the municipal authorities in charge of the water supply carry out at once our previous recommendation that a substantial wire fence be constructed around the area surrounding the springs and that this area be protected from surface wash by suitable and adequate drainage ditches or abandon the springs as a source of supply.
2. That a concrete floor or platform be constructed around the well from which water was being pumped by means of a well jack at the time of the inspection.
3. That a new pump house be constructed to house the machinery used in pumping from one or both wells located west of the village.
4. That the village authorities consider the development of one or more additional wells suitably located to be pumped from a central power plant, situated conveniently with respect to the village.

AMAGANSETT

An inspection of the water supply used by the Long Island Railroad in the unincorporated village of Amagansett, Suffolk county, N. Y., was made by Mr. Alfred Mullikin of this Division on August 8, 1921.

Amagansett is a village with a population estimated at 700 and is located in the town of Easthampton on the Montauk Branch of the Long Island Railroad, 105 miles east of New York city. The village is not provided with a public water supply, although 4 of its houses obtain water from the railroad water supply. The railroad waterworks are owned and operated by the Long Island Railroad under the direction of Mr. G. C. Bishop, Superintendent of Motive Power at Morris Park, and Mr. George Oswald, at Jamaica. The railroad water supply is derived from a 4-inch driven well located on the north side of the railroad track about 300 feet west of the railroad station. The well and the pump are located inside of a metal house 15 by 22 feet in plan provided with a brick floor. The well is 100 feet deep and has a 4-inch casing, the top of which is sealed. The strata through which the well passes consist of sand and gravel. The ground water level, which is normally 60 feet below the surface of the ground, is, during the hours of pumping, lowered an additional 10 feet.

From the well the water is delivered by pumping into a wooden water tank having a capacity of about 30,000 gallons. From the tank the water flows by gravity to a water column on the south side of the tracks and also through about 375 feet of 5-inch pipe and 200 feet of one-inch pipe to 4 village houses, one of which is occupied by an employee of the railroad company. Of the 5 service taps, one is metered. The average daily water consumption is approximately 60,000 gallons.

The water is used principally by the railroad to supply water for the engines and also for drinking and culinary purposes on the railroad coaches. The water supply is used for drinking purposes by the employees at the station. While the well is located on railroad property, the area around the well is not fenced to prevent persons or animals coming in the vicinity of the well and causing any possible pollution of the ground around the well. There are, however, no houses located within a distance of 400 feet of the supply. As far as known, the village is not provided with a sewerage system and disposes of its sewage by means of privies and cesspools.

It was, therefore, recommended in a report dated August 22, 1921:

1. That the railroad authorities maintain careful supervision over the supply at all times by:
   (a) Making frequent inspections of the area within a distance of 500 feet from the well to detect, and eliminate if possible, all sources of pollution which may exist.

(b) Enclosing an area at least 20 feet square around the well to prevent persons or animals from having access to the vicinity of the well and causing any pollution of the ground around the well.

(c) Constructing drainage ditches around the well to divert surface wash from the vicinity of the well.

AMSTERDAM (Typhoid Fever)

An investigation was made and data collected on the recent occurrence of typhoid fever in the city of Amsterdam, N. Y., by Mr. Earl Devendorf, assistant engineer of this Department, on November 17, 23, 28 and 30, and December 21, 1920.

Amsterdam has a population of 36,000 inhabitants and is located in the eastern part of Montgomery county. The Public water supply is derived from Hans creek on which several large storage reservoirs are constructed. As developed the public water supply is of a fairly satisfactory sanitary quality but, as is true of all surface supplies, is subject to accidental, incidental or wilful contamination by hunters, fishermen, lumbermen and other chance visitors upon the watershed.

Twenty-two cases of typhoid fever occurred, having dates of onset subsequent to October 6, 1920. The data relative to these cases will be found in Table No. 1 appended to the report. From this table it will be seen that practically all those who contracted the disease were employees of the McCleary, Wallin and Crouse carpet mill, all but three of the cases given being employed in the mill. An investigation made indicated that the cases occurred among those employees being supplied with, or having access to, the drinking water from one supply line.

Appended Table No. 2 shows the number of cases of typhoid fever grouped relative to ages in 10-year periods. This table shows that the cases were fairly well distributed according to ages among the adults but that no children had been ill with typhoid fever.

Appended Table No. 3 shows the number of cases of typhoid fever occurring on each milk route and the quantity of milk delivered by the principal dealers in the city. From this table it will be seen that the cases occurring on the various milk routes have been distributed approximately in proportion to the quantity of milk supplied by the various dealers and that no dealer has an extra large amount of cases occurring along his route.

Appended Table No. 4 shows the number of employees and the number of cases of typhoid fever occurring in the various departments of the McCleary, Wallin and Crouse mill.

A very pertinent fact in this respect is that the drinking water in these departments is supplied from one line.

On the afternoon of November 18, 1920, the engineer, in company with Mr. George Wolff, mechanic in the mill, made a detailed inspection of the piping system at the mill and the existence of a cross-connection between the drinking water line and a creek water line used for industrial purposes was discovered. This cross-connection consisted of a 2-inch globe valve and a 2-inch check valve. At the time of the inspection the globe valve was open. The engineer was later informed that the city pressure was usually higher at this point and that it was the practice to open the globe valve at times in order to use the higher city pressure to operate a hydraulic press which was connected to the creek water line. Between the meter located under the floor in the basement of building No. 1 and the check valve separating the creek water line from the city water line, a 1-inch feed main is taken off the city water pipe line and supplies the drinking water for the departments named above.

In view of the fact that the city water is available from mains used to supply the sprinkler system which are not connected to any drinking water foundations or taps throughout the plant, the engineer advised the authorities in charge of the mill to disconnect the creek water line from the city water line at the point where the drinking water line enters under the basement of building No. 1. This, the engineer was later informed, was done in the afternoon of Nov. 18, 1920. It was thought advisable to have this done as experience has shown that a single check and gate valve, similar to the above described installation, is not entirely reliable and has been known to fail on repeated occasions.

As a result of the above matter being brought to the attention of this Department, a letter was transmitted to the commissioner of public works of the city of Amsterdam, in which it was pointed out that a cross-connection between the city mains and any auxiliary fire main provided with water derived from polluted sources constitutes a potential source of danger. The Commissioner was, therefore, asked to have a survey made among the various mills in the city in order to determine the type of cross-connections which exists between the city mains and the private auxiliary fire supplies and to prohibit such cross-connections unless they are provided with double check valves, a blue print of which was furnished the Commissioner.

In a report upon the typhoid outbreak dated January 3, 1921, the following conclusions were drawn:

1. That a large number of typhoid fever cases occurred during the months of October and November, 1920, in the city of Amsterdam among the employees of the McCleary, Wallin and Crouse mill.
2. That the cases in the mill have been confined to those employees served by or having access to a drinking water line which was, previous to November 18, 1920, cross-connected to a pipe water line conveying polluted creek water and protected from the entrance of the polluted water by only a single globe and check valve and that on certain occasions it had been the practice to open the globe valve in order to take advantage of the higher city pressure to operate a hydraulic press.
3. That the history of the cases occurring in the mill seems to indicate that the probable cause of the outbreak was the failure of the check valve to operate properly, which allowed polluted creek water to enter the drinking water line at this point and that this appears to be confirmed by the results of analyses of samples of water collected from the taps in the mill.
4. That this cross-connection was removed on November 18, 1920, and that no further cases of typhoid fever have occurred among the employees of the McCleary, Wallin and Crouse mill since November 27, 1920, and at this date it seems probable that no further cases will occur from this source of infection.
5. That the various mills around the city having auxiliary fire systems connected to the city mains have been notified to either disconnect these systems or properly install double check valves between the city mains and their auxiliary fire systems.

It was, therefore, recommended:

1. That the authorities in charge of the public water supply carry out the former recommendations of this Department by immediately installing a chlorination plant to sterilize their public water supply.
2. That all cross-connections between the city mains and any auxiliary fire system be served if practicable and if not practicable at present be provided with double check and gate valves arranged in a concrete or brick manhole and provided with suitable gauges and drains arranged in accordance with the plans approved by this Department.

AMSTERDAM, N. Y.—TYPHOID FEVER OUTBREAK AMONG EMPLOYEES OF McCLEARY, WALLIN AND CROUSE MILL, NOV.-DEC., 1920

AMSTERDAM

An investigation of the public water supply of the city of Amsterdam was made by Mr. Earl Devendorf, assistant engineer in this Department, on April 20, 1921. Previous investigations of this supply have been made in 1909, 1915 and 1918, the reports upon which may be found in the Annual Reports of the State Department of Health for the respective years.

The water supply is owned by the city and operated under the Department of Public Works, of which Mr. Burr M. Stark is Commissioner. The supply is derived by gravity from Hans creek, the intake being located some 14 miles north of the city. Hans creek with its various reservoirs has a watershed area above the intake of 24¾ square miles with practically no population. While there is no resident population other than the caretaker's house existing on the watershed, there is considerable opportunity for pollution of the public water supply, as is true of all surface supplies, due to accidental or incidental contamination from trespassers on the watershed. Fishermen are allowed to fish on both the Cook and Glenwild reservoirs. Rules and regulations were enacted by this Department in 1890 for the sanitary protection of the public water supply. In addition to the possibility of pollution of the public water supply by the fishermen, the supply is, at times of rainfall and heavy runoff, very unsatisfactory from an aesthetic standpoint due to the high color and turbidity. In this connection it might be pointed out that the installation of a properly designed and efficiently operated filter plant would insure the furnishing of a supply that would be both of a satisfactory sanitary quality and of a good physical quality at all times.

The recent inspection disclosed that the conditions surrounding the supply were practically the same as existed at the time of the previous inspection with the exception that the city has caused double check valves to be installed at the mills where auxiliary fire supplies are used. These mills are the McCleary, Wallin & Crouse mill, the Sanford mill and the Shuttleworth mill. The installation of these double check valves is due to an outbreak of typhoid fever occurring among the employees of the McCleary, Wallin & Crouse mill in 1920, as a result of which the city authorities were advised by this Department to immediately cause double check valves to be installed between the city mains and the mains of those mills provided with auxiliary sources of supply for fire purposes, in order that no contaminated water might enter the city distribution system.

The city authorities still allow the cutting of ice upon the distributing reservoir which, as pointed out before, constitutes a menace to the purity of the supply since the opportunity for contamination from the workmen and horses engaged in cutting the ice is ever present. In the distributing reservoir algae growths during the past summer have been overcome by the use of copper sulphate, which was applied at three different times during the past summer, using a total of some 200 pounds.

It was, therefore, recommended in a report dated May 10, 1921:

1. That the city authorities rigorously enforce the rules and regulations enacted for the protection of their public water supply and endeavor to prevent fishermen or hunters from trespassing upon the watershed.
2. That the city authorities in charge of the water supply consider the matter of the installation of a filtration plant for treating the public water supply in order that a supply may be furnished the inhabitants which shall be at all times both of a satisfactory sanitary quality and a good physical quality.
3. That, as previously recommended, the cutting of ice on the distributing reservoir be discontinued or the supply be satisfactorily sterilized with liquid chlorine.
4. That adequate provision be made for diverting Bunn creek water from the distributing reservoir under all conditions of flow.

ANDES

A reinspection of the public water supply of the village of Andes, Delaware county, N. Y., was made by Mr. W. W. Young of this Division on October 27, 1921. A previous inspection of this supply was made in 1915 and the report thereon has been published in the Annual Report of the Department for that year.

Andes has a population of approximately 450, practically the entire population being served by the public water supply, which is owned and controlled by the Andes Water Company. The supply is derived from three springs. Water from these springs flows by gravity through pipes to a reservoir near the first spring. This reservoir has a capacity of about 125,000 gallons, and the water from it is delivered by gravity to the distribution system. In general the details of the waterworks system and the sources of supply remain as described in the previous report.

At the time of the last inspection it was recommended that suitable drainage ditches be constructed to divert surface wash from the Murray spring and that the land owned by the company about the spring be enclosed by a suitable fence for the purpose of excluding all persons, animals or fowls from the immediate vicinity of the spring. The recent inspection disclosed that land around the Spring No 3, or Murray spring, has been fenced but no ditching has been done. This spring is located in a steep ravine on the slopes of which, just above the spring, about 20 cows were noted grazing at the time of the inspection.

The Delaware and Northern Railroad Company does not obtain its water from the public supply but secures it through a pipe connection from a covered spring located on higher ground about 300 feet from the railroad depot. A small area above this spring was frequented by chickens, but if this were ditched and fenced off the spring would appear fairly well protected from opportunities for pollution from surface wash.

It was, therefore, recommended in a report dated November 5, 1921:

1. That spring No. 2 be cleaned and drainage ditches provided to divert all surface water from it. And the area around the spring fenced and posted to keep trespassers from coming in the vicinity of the spring and causing any pollution of the supply.
2. That the supply from spring No. 3 be either abandoned or entirely cleaned and protected from pollution by posting and fencing the area around the reservoir and by the construction of a dam and by-pass for the storm water from the ravine above it, or by other satisfactory means.
3. That the spring used as a source of supply by the Delaware and Northern Railroad Company be immediately protected from pollution by the construction of drainage ditches and fencing and posting an area around the spring for a distance at least 10 feet around the spring to prevent the danger of pollution by animals or visitors.

ANGELICA

A reinspection of the public water supply of the village of Angelica, Allegany county, was made by Mr. Alfred Mullikin, assistant engineer in this Department, on April 19, 1921. A previous inspection of this supply was made by the Division in the year 1917 and the report thereon published in the Annual Report of the Department for that year.

Angelica is located about 40 miles west of the city of Hornell. The present population is estimated at 1,000. Of the total population 90 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a Board of Water Commissioners of which Mr. T. S. Gillies is president and Mr. E. D. Dickson is superintendent.

The water supply is derived from a spring located on a private farm about 5 miles east of the village. From the spring the water is pumped to the village.

The spring is housed under a brick building and is partly covered with a concrete floor on which the pumping machinery rests. The entire floor and part of the surrounding ground is impregnated with cylinder oil, and it is possible that some of this oil may reach the supply. On the bank 25 feet east of the spring a gasoline tank is embedded and it is thought by the village officials that gasoline leaks from the tank and enters the supply. The farm house in which the pump attendant lives is located about 200 feet east of the spring. The barnyard is within 20 or 25 feet of the spring on the downstream side. About 100 feet northeast and above the spring at a higher elevation is a full earth vault privy which may be a source of contamination of the spring supply under certain hydraulic conditions of the ground water. There are no other houses located within 1,000 feet of the spring.

The village supply is cross-connected with the Pittsburgh, Shawmut and Northern railroad supply by a 6-inch pipe line. The Railroad Company obtains water from a dug well, which is 12 feet in diameter and 15 feet deep, having a masonry wall extending slightly above the ground surface and provided with a heavy wood cover. The well is located about 20 feet from the main course of Angelica creek. Water is pumped from the well to a tank near the railroad station.

In our previous report it has been recommended that the well adjacent to the village spring basin be covered and provided with a pump arranged in such a way that pumped water cannot flow back into the well; that the walls of the spring basin and the overflow pipe therefrom be raised to an elevation above flood waters; that when the spring basin walls are raised the pumping equipment be placed either in a separate building or that a portion of the spring house containing it be tightly sealed from the basin holding the spring water; that care should be exercised to prevent contamination of the ground water from nearby sources of pollution and if, after the carrying out of the above recommendations, future analyses indicate contamination, steps be taken to secure the control of the nearby farm buildings and remove such sources of contamination as may menace the quality of the supply, and, that in order to eliminate the necessity of pumping, a survey be made of the pipe line to the village in order to discover at what points the line rises above the hydraulic gradient and to correct such conditions as may be found to retard the free flow of water through the mains. From the recent inspection it appears that the previous recommendations have not been carried out.

In a report dated June 15, 1921, the following recommendations were made:

> 1. That the village authorities immediately carry out the previous recommendations of this Department as outlined in this report and if this is found to be impracticable a new supply be secured, free from all sources of pollution.
>
> 2. That in order to protect the village supply from contamination, all connections between the village supply and private supplies be severed, or, if this is not practicable, provided with double-check valves in accordance with the general plan approved by this Department.

ANGOLA

A reinspection of the public water supply of the village of Angola, Erie county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on December 15, 1920. A previous inspection of this supply was made by this Division in 1912 and a report thereon published in the Annual Report for that year.

Angola is located about 2 miles east of Lake Erie and 22 miles south of Buffalo. The present population of the village is estimated at 1,500, with an additional population in summer in the lake shore district of about 750, all of whom are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of Board of Water Commissioners of which Mr. Albert Candee is president.

The water supply is derived from Lake Erie and flows by gravity through a slow sand filter after which it is pumped into the distributing system. In general the details of the waterworks system remain as described in the previous report. The village authorities intend to install a meter at the filter plant to measure the consumption. They also contemplate voting on the advisability of adopting a new electric unit next fall on account of the failure in the past of the supply of gas which is now used to operate the pumping machinery.

From the recent inspection it appears that the previous recommendations of this Department have in part been carried out in that the fishing which takes place about two months of the year is done about 1½ miles out from the shore; that bathing is not indulged in closer than some 600 feet to the water intake; that while there are no signs to call attention to the restrictions preventing pollution of the lake in the vicinity of the water intake, the carrying out of regulations is imposed upon the pump attendant; that all cottages and camps on the water front are properly provided with privies for the disposal of sewage, as far as was noticed with the exception of one privy vault located some 500 feet south of the plant; that the filtration plant has not been enlarged or properly maintained to sufficiently increase it to a high standard of efficiency in that the amount of sand in the beds has been considerably varied and at times almost completely removed.

In a report dated February 7, 1921, the following conclusions were drawn:

1. That the water supply at the time of the inspection was of a very unsatisfactory sanitary quality.
2. That proper results according to the analyses of the water are not being produced by the filters.
3. That considerable fine sand from the lake is washed into the filter and on account of frequent cleaning out of the lake sand, the depth of sand varies considerably from time to time.
4. That the authorities in charge of the water supply have not carried out the previous recommendations of this Department, namely, that the filtration plant should be enlarged in order to maintain a higher efficiency in its operation and that the filters be operated at a rate which is considered good engineering practice.
5. That there remain certain possibilities for serious and dangerous contamination of the supply from the close proximity of some of the open vaulted privies to the plant.

It was, therefore, recommended:

1. That the filters be enlarged and reconstructed in order that lower rates may be maintained and a high efficiency obtained.
2. That a depth of not less than 30 inches of sand of uniform size be maintained above the crushed stone or gravel at all times.
3. That as far as possible all sources of pollution near the intake be eliminated.
4. That the supply be properly sterilized after filtration by the use of some sterilizing agent preferably liquid chlorine.

ANTWERP

A reinspection of the public water supply of the village of Antwerp, Jefferson county, N. Y., was made by Mr. W. W. Young of this Division on September 21, 1921. Previous inspections of this supply have been made in 1918 and 1920 and the reports thereon published in the Annual Reports of the Department for those years.

The village has a present population estimated at about 1,000 and is located in the northeastern part of Jefferson county. Of the total population about 90 per cent are served with the public water supply. The water works are owned and operated by the municipality under the direction of a board of water commissioners for whom Charles Bendis is superintendent.

The water supply is derived from the Indian river and is pumped directly into the distribution system. A chlorinator for the sterilization of the supply is connected with the suction of each of the two pumps. In general the details of the waterworks system remain as described in the previous reports with the important exception of the equipment of both pumps with liquid chlorine sterilization apparatus.

The watershed tributary to the supply is about 157 square miles, largely agricultural, and contains a scattered population of about 3,000, or about 19 per square mile. Beside the pollution from small settlements and from fields, pastures and houses and barnyards, 6 dwellings in the village discharge sewage into the pond above the intake.

In the previous reports of this Department it has been recommended that the supply be purified or a new source developed, that the advice of a competent engineer be secured and that pending the installation of a new or purified supply, the supply be continuously sterilized by the application of the proper amount of liquid chlorine. From the inspection it appears that the last recommendation is being complied with in part, but no active steps are being taken to comply with the other recommendations.

Samples of water were collected at the time of the inspection, the results of the analysis of which indicate that a sufficient amount of chlorine was not being applied to properly sterilize the water.

In a report dated October 6, 1921, the following recommendations were made:

> 1. That as previously recommended the authorities in charge of the public water supply at once engage a competent engineer to aid them in either procuring a new supply that shall be both sufficient in quantity and of a good sanitary quality, or provide a properly designed filter plant to treat the present supply.
> 2. That the rate of application of chlorine be increased and the chlorine applied in a continuous manner in sufficient quantity to show an excess by means of the starch iodide test, a copy of which is attached, in order that the supply may be effectively sterilized at all times.

ARKPORT

A reinspection of the public water supply of the village of Arkport, Steuben county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on April 20, 1921.

A previous inspection of the supply was made by this Division in the year 1917 and a report thereon published in the Annual Report of the Department for that year.

Arkport is located in the valley of the Canisteo river, 5 miles northwest of Hornell. The present population is estimated at 560. Of the total population 80 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees, of which Mr. C. A. Higgins is president and also the acting superintendent. The water supply is derived from Lime Kiln creek at a point about ½ mile northeast of the village. In general the details of the waterworks system remain as described in a previous report.

Lime Kiln creek begins northeast of the village near Daneville and flows in a southwesterly direction to the village and discharges into Canisteo river. The area of the watershed above the diversion dam is about

5 square miles. This area consists of a narrow valley formed between high, steep hills, of which 75 per cent is heavily wooded, the remaining land being used for agricultural purposes. The soil is mostly of loose gravel. There is very little trespassing on the watershed. There is a small amount of travel on the highways. There is one house occupied on the watershed about 2 miles above the intake which is provided with an earth vault privy so arranged as not to directly contaminate the supply. Another house on the watershed is not occupied. Careful inspections are made of the watershed monthly during the summer. Rules and regulations for the protection from contamination of the water supply were enacted by this Department in the year of 1915. The large part of the watershed is owned by the city of Hornell. The water is not treated in any manner to prevent vegetable growths. About ½ acre of land around the reservoir has been fenced and posted. The reservoir is not covered. The water from it flows through a 10-inch cast-iron pipe to the village distributing system.

In our previous report it has been recommended that consideration be given to the installation of a purification plant consisting of filters and supplementary sterilization with liquid chlorine, that in order to render the supply safe at all times for potable purposes and pending the installation of a complete purification plant, apparatus be provided and the water be sterilized with liquid chlorine. From the recent inspection it appears that the previous recommendations have not been acted upon. The village supply is not cross-connected to any private supply. The P., S. & N. R. R. used the village supply for drinking purposes.

In a report upon an inspection of the public water supply of Arkport, dated May 23, 1921, the following conclusions were drawn:

1. That the water supply, although from a surface source and not treated, is of a relatively satisfactory sanitary quality.
2. That there are certain opportunities for serious contamination of the supply from accidental, incidental or wilful pollution from inhabitants living near or passing over the watershed.
3. That the village authorities in charge of the water supply have not carried out the previous recommendations of this Department, in that consideration has not been given to the installation of a purification plant and sterilizing apparatus.

It was, therefore, recommended that the village authorities carry out the previous recommendations of this Department regarding the treatment of the supply as outlined above.

ARKVILLE

A reinspection of the public water supply of Arkville, N. Y., was made by Mr. W. W. Young of this Division on October 26, 1921. Previous inspections of this supply were made in 1909 and 1917 and reports thereon were published in the Annual Reports of the Department for those years.

Arkville has a population of about 400 and is located in the eastern part of Delaware county. About 90 per cent of the population are served by the public water supply. The waterworks are owned and operated by the Arkville Water Company of which Mr. Henry M. Cowan is president. The water supply is derived from a mountain brook about 1 mile southeast of the village from which the water flows to the consumers by gravity. In general the supply is practically the same as described in the previous reports.

The watershed above the intake is about ¾ of a square mile in area, contains no houses, and is subject only to such pollution as might be received from occasional passing of animals or persons over the watershed.

In a report, dated November 18, 1921, it was concluded that, at the time of the inspection the public water supply of Arkville was of a fairly satisfactory sanitary quality. It was, therefore, recommended that the water company continue to maintain constant and careful supervision of the sanitary conditions of the watershed and intake in order that the supply may at all times be free from contamination.

ATTICA

A reinspection of the public water supply of the village of Attica, Wyoming county, N. Y. was made by Mr. Alfred Mullikin, assistant engineer in this Department, on December 18, 1920. Previous inspections of this supply were made by this Division in the year of 1908 and 1915 and reports thereon published in the Annual Reports of the Department for the years 1908 and 1916, respectively.

Attica is located on Tonawanda creek about 30 miles east of the city of Buffalo. The present population is estimated at 2,000, of which 98 per cent are served with water from the public water supply. The remaining 2 per cent are furnished by private wells. The waterworks are owned and operated by the municipality under the direction of the village board of trustees, of which Mr. Harry Morgan is president. The water supply is derived from an impounding reservoir formed by a dam constructed across Crow creek about 2½ miles south of the village. The reservoir has a capacity of some 12,000,000 gallons. From the reservoir the water is conducted by gravity to pressure mechanical filters which are located in the southern part of the village. From these filters the water flows directly into the distributing system. There is no record kept or any measure made of the water consumption, but based upon an assumed per capita consumption of 80 gallons the average daily domestic water consumption is approximately 156,000 gallons, or the total water consumption, including that used by the railroad, about 290,000 per day.

The village is not provided with a sewerage system, there being about 100 open cesspools and privy vaults. Seventy-five per cent of the population of the village dispose of their sewage by means of 7 private sewers which empty into Tonawanda creek. There are a number of wells, 70 per cent of which are within 100 feet of privy vaults. Many of these privy vaults are of concrete and most of the privies have been screened. Each year notices are sent to residents of the village to instruct then how to clean and care for privies, cesspools, etc., and it is claimed by the health officer that such instruction has produced good results.

In general the details of the waterworks system remain as described in the previous reports with the exception of the following changes: In 1918, the village took over the water supply which was formerly owned and controlled by the Attica Water, Gas and Electric Company; it has laid some new pipe consisting of one-half of a mile of 8-inch cast-iron pipe; two new filter units of the Roberts horizontal pressure type have been added to the filter plant and are located in the same building with two old vertical pressure filters of the New York Continental type; the artificial pond located near the Westinghouse manufacturing plant and into which waste water from this plant drains has been abandoned as a source of supply for the village for purposes of fire protection. The village authorities intend to construct a reservoir on Bennington hill, to supply the west side of the village, as soon as the prices decline.

The watershed of Crow creek has an area of about 9.3 square miles and, as pointed out in previous reports, is subject to considerable pollution. There are no water rules or regulations for the protection of the watershed. The reservoir is fenced and no ice is cut during the year. As this reservoir has not sufficient elevation to maintain an entirely satisfactory pressure in the village the authorities have considered the development of another source of supply from Stony brook which is at a greater elevation and would therefore provide sufficient pressure for all purposes but is some 8 miles south of the village and would therefore require the construction of a long force main. The Stony brook watershed has an area of approximately 9.7 square miles and a dry weather flow of 47,300 cubic feet or 354,000 gallons per day. The yield of the 2 watersheds, Stony brook and Crow creek, is practically the same. No active steps have yet been taken toward the development of this supply.

In our previous reports it has been recommended that the water company proceed at once to so improve the present supply or to so develop a new supply as to furnish the village with pure and wholesome water; that in case the water company fails to make the above improvements the village consider the question of securing a satisfactory supply of pure water either by taking over and improving the present supply or by securing a new and independent supply; that in view of the uncertainty as to which of the above courses is the best or the most economical to pursue, the village retain the services of a competent sanitary engineer to make a study of the various problems outlined in the report and advise them as to the proper procedure to follow before determining the proper course to follow: that pending the development of a satisfactory supply by the village the sanitary quality of the present supply be protected by removing, insofar as possible, the sources of pollution from the present watershed and effectively sterilizing the water with liquid chlorine or hypochlorite. In connection with the development of the supply from either Crow creek or Stony brook it has been pointed out that it would be necessary to remove certain sources of pollution from the watershed and in order to effectively do this it seems advisable that application be made to this Department for the enactment of rules and regulations for the protection of the supply from contamination.

From the recent inspection it appears that the previous recommendations have in part been carried out in that the village authorities, while they have not developed a new supply, have taken over the present supply from the water company. They have not, however, installed apparatus for the sterilization of the water by the application of liquid chlorine or by some other satisfactory method.

In a report upon an inspection of the supply the following recommendations were made:

1. That the village authorities install suitable chlorinating apparatus and effectively sterilize all water delivered to the consumers by the application of the proper amount of liquid chlorine.
2. That alum be applied to the water at all times in such proportion as may be found necessary for the efficient operation of the filters.
3. That the village authorities continue their careful supervision of the watershed and remove as far as possible all sources of possible pollution.
4. That if any difficulty is found in removing these sources of possible pollution, the authorities apply to this Department for the enactment of rules and regulations for the protection from contamination of the water supply of the village.

AUBURN

An investigation of the public water supply of the city of Auburn was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 16, 1920.

Auburn is a city of approximately 38,000 inhabitants, located in the central part of Cayuga county some 30 miles southwest of Syracuse. It is on the Auburn branch of the New York Central railroad, the Lehigh Valley railroad and the New York State Electric railroad. The city is served by a system of separate sewers, the effluent of which is discharged into two small brooks tributary to the Owasco lake outlet, after treatment, in a disposal plant consisting of grit and screen chambers, settling tanks and contact beds.

The original water supply was furnished by the Auburn Water Works Company which constructed the plant in 1865, when the population was approximately 14,000. The city entered into negotiations in 1892 for the purchase of the waterworks and finally took over the system in 1894. The supply was derived by pumping from Owasco lake outlet.

The waterworks system has been constructed and operated under a board of water commissioners, but on January 1, 1921, the city of Auburn took over the affairs of the water board under the provision of the city charter and consolidated the water department with the other city departments under the supervision of the city manager, Mr. John P. Jaeckel. Mr. George A. Lewis is chief engineer and superintendent of the water department. The original water supply of the city of Auburn was derived by pumping from the lake outlet at a point near the state dam about 9,000 feet below the lake. The water was pumped from here directly into the distribution system. In 1883, on account of the dangers of pollution in this outlet, a 24-inch pipe was extended upstream into the lake and a second pumping station erected on the pier 1,000 feet from the shore with a 30-inch wrought-iron intake extending 600 feet further into the lake at a point where the water was about 15 feet deep. The water was pumped to the lower station over a ridge about 17 feet above the lake level where it was again pumped to the distribution system by the upper pumping station. In 1907 a new intake, 36 inches in diameter, was carried out into the lake a distance of 1,875 feet to a point where the water was 40 feet deep, and this intake has been in use since it was laid, although the old intake is still in existence.

At present the water is pumped from the lake to the purification plant where it is filtered and later pumped to the public distribution system. The consumption varies from 5 to 7 million gallons per day. The average daily pumpage for the year ending December 31, 1919, was 6,214,847 gallons or 158 gallons per capita per day. For the year 1918 the pumpage amounted to 178 gallons per capita per day. This decrease in pumpage was largely due to the installation of meters during the year 1919, when the percentage of services metered was increased from 48 per cent to 83 per cent. At the present time the city has on hand between 400 and 500 meters which will be installed as opportunity permits. The pressure at the pumping station is 60 pounds per square inch while in the city it varies from 80 to 100 pounds per square inch. No storage is provided.

At the time of the inspection the matter of cross-connections between the public mains and any private fire supplies was taken up and it was found that all cross-connections are equipped with double check and gate valves placed in accessible concrete manholes. Frequent inspection should be made of the cross-connections in order to see that they are all in proper operating condition.

The upper pumping station was installed in 1904 and is used for pumping raw water to the purification plant. It is equipped with one Snow double-acting cross-compound steam pump, having a capacity of 10,000,000 gallons per day, and with a 7,500,000 gallon Gaskill horizontal compound pump as an auxiliary. The lower pumping station, used for pumping the filtered water to the city mains, is equipped with a 7½ million gallon Gaskill pump and a 10,000,000 gallon R. D. Wood double-acting pump. When water-power is available the pumps are operated by three water turbines which are operated under a small head ranging from 10 to 14 feet. At present, when the water turbines are used, the engine is allowed to run free. It is proposed to disconnect the steam engine from the pump and to supply a connection that will permit the pump to operate with the water wheel alone without operating the engine.

Owasco lake, from which the supply is obtained, is 10.9 miles in length and about 1 mile in width throughout its entire length and has a surface area of nearly 10 square miles and a total capacity of approximately 200,000 million gallons. Its average depth is 96 feet and its maximum depth is 177 feet. The entire drainage area of the lake is approximately 200 square miles and has a population of approximately 10,000 persons, or about 50 per square mile. This includes the population of the three villages of Moravia, Groton and Locke and the two villages of Niles and Owasco. None of these villages have a public sewer system, although there are some private sewers in use. On the banks of the lake are about 200 cottages and some small hotels, the waste from which constitutes a menace to the purity of the water supply.

In order to minimize this opportunity for pollution rules and regulations for the sanitary protection of the public water supply of the city of Auburn were enacted in 1906, and the entire watershed is patroled by inspectors of the water board, who have in a thorough manner enforced the rules. In this connection the privies have been moved, watertight boxes have been substituted for leaky ones, barns and barnyards have been removed and cesspools provided. The water board has at times encountered opposition to the enforcement of these rules and has had several notable law suits concerning the enforcement of these rules and regulations, which have been decided in favor of the city.

In order to minimize the danger resulting from this pollution hypochlorite of lime was used to sterilize the public water supply in May, 1911. The operation was not continuous and was only used at such times as analyses indicated that pollution was reaching the supply at the intake. In October, 1913, liquid chlorine was substituted for hypochlorite of lime in sterilizing the supply. The liquid chlorine was applied by a Leavitt-Jackson chlorinator. The gas was fed through a distributor placed in a suction well and when used was applied at the average rate of approximately .3 p. p. m. In 1919 a Wallace and Tiernan dry feed manual control chlorinator was purchased. Just previous to the time of the inspection chlorine was applied for 5 days, from December 10th to the 14th, inclusive, at an average rate of .14 p. p. m.

The question of the filtration of the public water supply was before the public for a number of years before it was finally approved, and contracts for the construction of a filter plant were finally let in 1917. Due to the scarcity of labor and very high prices of material throughout the period of the war the contractors were delayed and construction finally stopped in the spring of 1919, as the contractors were unable to finance further construction. The city itself then undertook to assist the contractors in financing further construction and the purification plant was finally finished and put in operation on July 8, 1920.

The filtration plant is located near the outlet, at a point just above the lower pumping station, and consists of 4 slow sand filters each having an area of .395 acres, giving a total area of 1.56 acres. Water is maintained at an average depth of approximately 5 feet above the sand. The filters are underlaid with drains on top of which is placed 1 foot of graded gravel and 3 feet of sand. No sample of the sand was obtained and no information was available as to the effective size or the uniformity coefficient of the sand used in the filters. The filter beds are operated at a rate varying from 1,000,000 to 7,000,000 gallons per acre per day. The average rate of filtration for the month of November, 1920, was 3.8 million gallons per acre per day, while the maximum was 5.16 and the minimum 2.56 million gallons per acre per day. The initial loss of head is 0.5 feet and a bed is cleaned when the loss of head becomes 5 feet. One sand washer for each two filter units is provided for washing the sand scraped from the bed at times of cleaning. Data obtained from the operator show that 5,485 gallons of water per cubic yard of sand washed were used in cleaning the sand from Bed No. 1. During the time the plant has been in operation it has been the practice to scrape the beds approximately once every two months, and it is estimated that to the present time approximately 1/10 of a foot has been removed. In this connection care should be taken not to remove too great a depth of the sand without replacing the sand, as the depth of the filter sand would be reduced to such a point as to seriously affect the effective purification afforded by the filter beds. Loss of head gauges connected to Venturi meters and rate controllers for maintaining a proper rate of filtration are provided for each filter unit. At the filtration plant a laboratory is maintained and a competent operator, experienced in the operation of water purification plants, is employed to supervise the operation of the plant. Daily analyses were begun in the laboratory on September 8, 1920.

The efficiency of the operation of the filter plant as based on the average results of analyses made at the laboratory at the plant for the month of November, 1920, indicate a color removal of 31 per cent and a turbidity removal of 100 per cent. The bacterial removal based upon the average results of the gelatine count for the month of November is 96.7 per cent. Out of 26 daily analyses made during the month of November B. coli were found present in 23 of the 10 cc.; 10 of the 1 cc. and 3 of the 1/10 cc. samples of the raw water and in none of the filtered water samples.

At the time of the inspection samples of the public water supply were collected and sent to the Division of Laboratories and Research for analyses.

The results of the analyses of the raw water collected at the filter plant show a hard water having little color and no turbidity. The amount of nitrogen present in its various forms is moderate with the exception of that as nitrite. The amount of oxygen consumed and the chlorine content are also moderate. The results of the bacterial examination show high total bacterial counts which may be in part due to the multiplication of various forms of water bacteria as a result of the delay in transit, since the samples were five days in reaching the laboratory. Organisms of the B. coli type were absent in all of the inoculations examined, indicating that the raw water was free from any active contamination at the time of the inspection.

The results of the examination of the filtered water collected from the lower pumping station and from a tap in the city show a hard water having no color or turbidity. The amount of nitrogen present in its various forms is moderate, as is the oxygen consumed and chlorine content. The results of the bacterial examination show a rather high total bacterial count due perhaps to the multiplication of various forms of water bacteria as a result of the delay in transit. Organisms of the B. coli type were absent in all of the inoculations examined, indicating that the supply was free from any active contamination.

In view of the above facts, the following recommendations were made in a report dated March 9, 1921:

1. That the authorities in charge of the public water supply continue their careful supervision of the conditions on the watershed and employ the necessary inspectors in order that no insanitary conditions may be allowed to exist.
2. That the authorities in charge of the public water supply continue to operate the purification plant under the supervision of a competent operator, in order that a water of satisfactory sanitary quality shall at all times be supplied for the consumption in the city.

AVOCA

A reinspection of the public water supply of the village of Avoca, Steuben county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on December 13, 1920. A previous inspection of this supply was made by this Division in the year 1914 and a report thereon published in the Annual Report of this Department for that year.

Avoca is located in the north central part of Steuben county in the valley of the Cohocton river. The present population is estimated at 1,100, of which 95 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality, under the direction of a board of trustees of which Mr. Angelo Walker is president and Mr. W. C. Gallup is superintendent.

The water supply is derived from several springs located in the valley of the small stream known as Cotton creek, at a point about 1¼ miles in a direct line west of the village. From these springs the water is let to two central spring houses before it is discharged into the distributing system. The spring houses measure about 12 by 14 feet in plan and are provided with a concrete floor having a collecting chamber. In 1 house the collecting chamber is 4 feet in diameter and in the other 6 feet in diameter.

The spring water from the masonry reservoir is delivered by gravity to a distributing system of some 7 miles of pipe ranging from 2 to 8 inches in diameter. Each fall the flow of water from the springs is supplemented by opening a valve and allowing creek water to enter the masonry reservoir. The object of doing this is to have sufficient water storage for fire purposes as the yield of the springs is less at this season. The pressure in the municipality is approximately 50 pounds per square inch. The service connections in the village are not provided with any meters. The average daily water consumption is not known but based on an assumed per capita consumption of 80 gallons per day probably amounts to 83,600 gallons. In general, the details of the waterworks system remain as described in the previous report.

There are 2 reservoirs; 1 for the collection of creek water and the other for the storage of spring water. The creek reservoir has a storage capacity of approximately 1,000,000 gallons of water. A stone reservoir, which is located inside of and at the extreme west end of the creek reservoir is for the storage of spring water and has a capacity of about 230,000 gallons. It is provided with a cement bottom. It is cleaned every year and was cleaned twice during the year 1920. There seemed, however, to be evidence of some algae growth on the bottom. The reservoir is not treated to prevent such growths. A fence has not been provided to prevent trespassing. Ice is not cut from this reservoir but it is cut from the creek reservoir. The southern masonry wall of the spring reservoir contains a pipe which connects the spring reservoir with the creek reservoir. At the northern end is an 8-inch submerged outlet pipe turned up and provided with a screen cover. On the outside of the 18-inch concrete wall which forms the north side of the creek and spring reservoirs there seemed to be several leaks but it could not be ascertained whether these leaks came from the creek supply or from the spring supply.

The area of land owned by the village in the vicinity of the spring reservoir consists of about 40 acres. There were no direct sources of pollution noticed at the spring reservoir outside of the possibility of leakage of the creek water through the masonry wall and the entrance of the creek water through the connecting pipe from the creek supply.

On top of the ground above each spring a concrete apron is provided as a protection from pollution of the supply but it is so constructed that surface wash from the hills in one case and from the highway in another, can collect on this concrete apron and be diverted directly into the springs. There are only 2 or 3 farm houses within one-half of a mile of Cotton creek and probably only a small amount of pollution of the creek water occurs from surface wash near these buildings and from manure piles and animal enclosures. The watershed area of the creek is rather hilly and devoted to agricultural purposes. There is no doubt that cattle have access to the stream from time to time. The area in the vicinity of the springs, which is owned by the village, is apparently free from such sources of contamination, as apparently no cattle are pastured thereon.

In our previous report it has been recommended that the village make the inner reservoir water-tight to prevent the inflow of creek water, as the latter, while of a reasonably safe and desirable source of water supply, is probably inferior to the spring water supply; that a separate intake be laid for the creek water supply to be used independently of the spring supply and only in emergencies; that a strict supervision and frequent inspection be made not only of the springs and the surroundings, but also the watershed of the creek above the reservoir to protect the water from accidental pollution; and that the local authorities be cognizant of the occurrence of sickness on the watershed in order that they may take immediate measures to prevent any possibility of infection of the water supply; that if the Board of Water Commissioners experience any difficulty in preventing any careless or wilful or unnecessary pollution of the water supply that they apply to this Department for the enactment of rules and regulations for the sanitary protection of the public water supply of the village; that measures be taken to prevent leakage or waste of the spring water supply; that in case it becomes necessary to use the creek water supply, this water be subjected to some method of sterilization. From the recent inspection it appears that these recommendations have not been acted upon.

In a report dated February 1, 1921, upon an inspection of the supply, the following recommendations were made:

1. That the leaks in the spring water reservoir be repaired and that the reservoir be kept clean and free from algae growths at all times.
2. That the walls around the spring be extended above the cement apron surrounding them in such a manner as to prevent surface wash entering the spring supply.
3. That a careful supervision be exercised over the creek and spring watershed to determine and eliminate, if possible, all direct sources of pollution.
4. That the authorities in charge of the water supply immediately carry out such recommendations of our previous report as have not yet been carried out, and which are enumerated in this report.

BALDWINSVILLE

A reinspection of the public water supply of Baldwinsville, N. Y. was made by Mr. William Young of this Division on September 23, 1921. Previous inspections of this supply have been made in 1918 and 1920 and the reports thereon published in the Annual Reports of the Department for those years.

Baldwinsville has a present population estimated at 3,700 and is located about 12 miles northwest of Syracuse. Of the total population some 90 per cent are served with the public water supply. The waterworks are owned by the municipality and operated under the direction of a board of water commissioners of which Mr. Abner Tooley is president. The water supply is derived from a dug well 20 feet in depth and 20 feet in diameter with a steel casing and roof, located near the southwesterly limits of the village. From the well the water is delivered by pumping through the distribution system.

A number of sewers pass within a relatively short distance of the well and constitute a menace and potential source of pollution of the well.

In previous reports on the village water supply this Department recommended frequent analyses, consideration of a new well about 1,000 feet away and the immediate installation of a chlorine sterilization plant for use until a new source of supply was obtained.

The village officials present at the inspection suggested in lieu of this, the abandonment of all four of the tile sewers, near the well, and the construction of an entirely new system of iron pipe sewers, laid with watertight leaded joints. The branch sewer from Seneca street and the sewer in front of the waterworks property, are proposed to be laid at a considerable distance farther from the well than at present. The officials also suggested the opening of a street to avoid the passage of traffic on the lane or road now passing within a few feet of the well and also the purchase of several acres of ground adjoining the present properties, to lessen the danger of accidental or other contamination of the water from houses which otherwise might be built on this ground.

It would appear that if properly laid, a system of iron pipe sewers taken in connection with the removal of the thoroughfare, might satisfactorily remove the more imminent dangers of the well from pollution; but in view of the fact that there are 3 or 4 dwellings already located within between about 100 and 200 feet of the well, the water in which is 12 or 14 feet beneath the ground surface, careful inspection of the vicinity should be maintained and any sources of pollution found to exist should be removed.

The securing of all possible additional land within a radius of 500 feet of the well, particularly where the ground lies either higher than or to the west of the well seems desirable as does also the fencing of the property and the strict enforcement of regulations concerning the sanitary care and disposal of any slops, refuse or other organic matter especially within the radius mentioned. The posting of such regulations and the fencing off of the immediate vicinity of the well would be a further safeguard against pollution.

It was recommended in a report dated October 17, 1921:

1. That the municipal authorities in charge of the water supply either carry out at once the previous recommendations of the Department including the moving of the well or securing another supply and temporary sterilization of the water, or
2. That the village authorities divert traffic and trespassers from the vicinity of the well and replace all tile sewers within 200 feet of the well with tightly jointed iron pipe laid through watertight manholes in undisturbed ground, plans for which sewers should be submitted to the State Engineer for approval and temporarily sterilize the well water until such replacement work is completed.

BATAVIA

A reinspection of the public water supply of the city of Batavia was made by Mr. W. J. Erickson, sanitary inspector in this Department, on April 15, 1921. Previous inspections of this supply were made in 1912, 1915 and 1918 and reported upon in the Annual Reports of the Department for the respective years.

Batavia is a city of 15,000 inhabitants, located in the central part of Genesee county. A comprehensive sewer system is provided, discharging into the Tonawanda creek, after passing through a disposal plant consisting of an Imhoff tank and sprinkling filters. Approximately 95 per cent of the population uses the public water supply which is owned by the city and operated under the direction of the common council, in direct charge of Mr. I. J. Carmichael, city clerk. The supply is derived from Tonawanda creek, the intake being located in the southern part of the city. After passing through a gravity mechanical filtration plant supplemented by sterilization, it is pumped into the distribution system.

The intake is located just off the east bank of the Tonawanda creek about 100 feet north of the Lehigh Valley Railroad bridge. A 20-inch cast-iron pipe conducts the water by gravity to the suction well located at the filter plant about 600 feet distant. From this well the water is lifted by the low lift pumps to the coagulation and sedimentation basin located adjacent to the filter plant. The coagulation and sedimentation basin has a capacity of approximately 500,000 gallons and provides an average detention period of about 8 hours. The alum is dissolved in two concrete mixing tanks from which it is fed by gravity through constant level orifices to the raw water at rates varying from 1.5 grains to 12 grains per gallon according to the condition of the raw water.

After sedimentation the water flows by gravity onto six units of gravity mechanical filters of the Pittsburgh filter type. The filters have a capacity of about 500,000 gallons each when operated at a rate of about 125,000,000 gallons per acre per day. Venturi rate controllers regulate the operation of the filters. After filtration the water enters two clear water basins with a capacity of 35,000 gallons.

Liquid chlorine is applied to the filtered water in the discharge line from the clear water basin in such a way that all water is treated. The apparatus consists of a Wallace and Tiernan chlorinator of the automatic control feed type. Scales are provided for the checking of the weight of the chlorine used. At the time of the inspection about 0.3 parts of chlorine per million by weight were being applied. Complete records of the operation of the plant are kept.

Daily tests for turbidity, color and alkalinity are made at the pumping stations. Bacterial analyses of samples collected at points where it is deemed advisable three times a day and analyzed at the county laboratory.

In a report dated May 4, 1921, it was recommended that the filtration and sterilization plant be so operated as to effectively treat the water at all times.

BATAVIA (New York Central Railroad)

An inspection of the sanitary condition of the water supply derived from the New York Central well located at Batavia was made by Mr. W. J. Erickson, sanitary inspector in this Department, on April 15, 1921.

The well is located under the baggage room of the New York Central depot and was developed by driving a 1¼-inch pipe to a depth of about 50 feet, the last 10 feet of which is said to be through rock. The pipe extends about 3½ feet above the floor of the baggage room. The water is drawn by means of a small hand pump.

The floor of the baggage room is tight so there is little probability of any direct surface wash entering the well. The well is, however, located in a thickly populated section and there are many possibilities for contamination reaching the ground water tributary to the well from leaky sewers in the nearby streets. The sewer from the depot itself passes within 50 feet of the well.

Two weeks prior to the time of the inspection the use of the water for drinking purposes by the public in the depot was discontinued, the well water being objectionable on account of its sulphur taste and odor. Since that time the railroad company has shipped water from Rochester in milk cans. Two water coolers are kept filled with water from these cans. Though the water of Rochester is of assured purity, the method of transportation with its many opportunities for contamination cannot be considered sanitary. No information could be obtained as to whether or not the cans are sterilized after being used.

The well with its unsatisfactory location and the high hydrogen sulphide content of its water cannot be considered as a satisfactory source of supply nor can the method of securing a supply by transporting water from Rochester be considered satisfactory. The city supply with efficient purification is of satisfactory quality and it would seem advisable, in order to protect the public, that the railroad should use the city water supply.

In a report dated April 30, 1921, it was recommended:

1. That on account of the disagreeable tastes of the water and the unsatisfactory location of the well, the well be abandoned.
2. That on account of the numerous opportunities for contamination in the handling of the water shipped from Rochester, this method of supplying water be abandoned.
3. That the New York Central railroad install sanitary drinking fountains and connect with the Batavia city supply.

BATH

A reinspection of the public water supply of the village of Bath was made by Mr. W. J. Erickson, sanitary inspector, on April 13, 1921. A previous inspection was made of this supply in 1917, the report upon which is published in the 38th Annual Report of this Department.

Bath, which is a village with a population of about 4,000, is located in the central part of Steuben county. The village is not served by a comprehensive sewer system. A private system serves the county buildings and a few others and discharges directly into the Cohocton river. The water supply is owned and operated by the Bath Waterworks Company of which Mr. Robert E. Kizer is president. The supply is derived from a dug well located in the northwestern part of the village, from which the water is pumped through the distribution system to a standpipe located on a hill in the southwestern part of the village. The consumption ranges from 200,000 gallons to 300,000 gallons daily.

The well is 20 feet in diameter and 28 feet deep and is provided with a steel casing extending from the bottom to about a foot above the ground surface. It is covered with a conical wooden roof. The topography is such that the surface drainage is diverted around the well to a pond located just southwest of it. A house and cesspool are 300 feet and a barn 200 feet from the well. It was said that a pipe was laid with the intention that should there be any necessity to augment the supply it could be done by pumping from this pond. The water in the pond is subject to runoff from an area which is comparatively densely populated and to the overflow from the Cohocton river at times of floods. It becomes very stagnant during the summer, and is very objectionable.

In a report on the inspection of the supply dated May 4, 1921 the following recommendations were made:

1. That the vicinity of the well be maintained in a sanitary condition at all times in order to prevent any possible contamination.
2. That the pumping house be kept in a neat condition and that the pumps be kept clean and as free from oil as possible.
3. That the suction line to the pond be disconnected and the end near the suction line to the well be sealed.

BEACON

A reinspection of the public water supply of the city of Beacon was made by Mr. William Young of this Division on July 11, 1921. Reports on previous investigations were published in the Annual Reports of the Department for the years 1912, 1913, 1918 and 1919.

Beacon, a city of some 11,000 inhabitants, is located in the southern part of Dutchess county. The waterworks are owned and operated by the municipality under the direction of the superintendent of water.

The city water supply is derived by gravity from Melzingah, Mount Beacon and Greer brooks. At times water from Fishkill creek has been delivered into the distribution system by pumping after chlorination. The total water consumption amounting to approximately 550,000 gallons per day or 55 gallons per capita is distributed by gravity.

The watershed area of the Mount Beacon supply is 0.2 square mile. At the Pocket reservoir the watershed area, inclusive of the Mount Beacon watershed is 0.7 square mile. The Melzingah supply has a watershed area of 1.25 square miles. Opportunities for pollution of the supply exist at Mount Beacon from the caretaker's cottage and a private cottage; at the Melzingah supply from several cottages and at the Pocket reservoir from numerous cottages located on the rocky and precipitous slopes above the reservoir. At the time of the inspection the watershed was not visited but conditions are said to remain the same as described in the former report.

The previous recommendations of the Department in regard to increasing the supply by new or additional storage, improvement of sanitary conditions on the watershed, the sterilization of the auxiliary supply from Fishkill creek, frequent inspections of the watershed, the enactment of rules and regulations by this Department, the chlorination of the upland supplies in the summer and if the yield from the upland supplies continued insufficient, the filtration and sterilization of Fishkill creek for permanent use, have not been carried out.

In a report upon the inspection of the supply dated August 29, 1921 it was recommended that the authorities in charge of the water supply carry out such of the previous recommendations of this Department as have not been acted upon.

About the middle of November, this Department was advised by the local health officer of the city of Beacon that water was being pumped from the emergency supply from Fishkill creek into the city mains and requested that a representative of this Department be sent to instruct the officials in charge as to the proper amount of chlorine to be applied to the water. Mr. Albert Howd was accordingly detailed to make an investigation and learned that the Beacon and Melzingah reservoirs had become depleted of water and that on November 3 the water was pumped into the mains from Fishkill creek.

The pumping equipment which was new, consisted of a three cycle centrifugal Worthington pump which was being operated at the rate of about 500 gallons per minute. The chlorinator for sterilizing the water was manufactured by Wallace and Tiernan and is a manually controlled solution feed chlorinator of the pulsating type.

The chlorine was being applied to the water at the rate of 0.18 parts per million parts of water which was entirely insufficient to properly sterilize the water from Fishkill creek. The amount of chlorine applied to the water was gradually increased until it was being applied at the rate of about 0.8 parts per million when a slight excess of free chlorine was obtained in the treated water. Instructions for operating the chlorinator and for making the starch iodide tests for free chlorine were given to the superintendent of water.

BOONVILLE

A reinspection of the public water supply of the village of Boonville was made by Mr. Earl Devendorf, representative of this Division, on September 13 and October 19, 1921. Previous investigations of the supply have been made by this Division in 1916 and 1918, and reports thereon published in the Annual Reports of the Department for the years 1917 and 1918, respectively.

Boonville is an incorporated village, with a present population estimated at 2,000, located in the northern part of Oneida county, 35 miles north of Utica. Practically all of the inhabitants of the village are served with the public water supply. The waterworks are owned by the village and operated under the direction of a board of water commissioners, of which Mr. C. O. Bridgman is superintendent. The water supply is derived from Kingsbury and Wolf creeks, on which impounding reservoirs have been located some two miles northwest of the village. From the reservoirs the water is delivered by gravity through the distribution system.

The inspection was made as a result of a telephone conversation with Mr. George Hodges, biologist, of Utica, who had been engaged by the village authorities to advise them. He informed the Department that the village was experiencing a shortage of water, and it would be necessary to use the Forestport feeder as an emergency supply. Water was pumped from this feeder as an auxiliary source of supply from September 4th to the 24th, inclusive. On September 13, Mr. Devendorf, of the Department, visited Boonville, in company with Mr. Hodges, and inspected the emergency pumping plant and chlorination apparatus. A steam fire engine had been borrowed from the city of Utica, and was being used to pump water into the village mains from a barrel located in the side of the canal, and which was receiving water from the feeder through a wooden conduit formed of boards fastened together by means of screws and sealed with white lead. This conduit probably was some 150 feet in length and extended across the canal and into the mouth of the feeder, in order that none of the polluted canal water would be pumped into the village mains. There was a possibility, however, of this conduit leaking through warping of the board, in which case the water from the canal itself would enter the conduit and thereby be pumped into the village distribution system. It was learned that several sewers were emptying into the canal at a short distance from the point where the barrel was located.

Liquid chlorine was being used for sterilizing the supply. A cylinder of chlorine had been placed on a pair of platform scales located alongside of the pumping plant, and the gas was being fed through a small glass bottle into the wooden barrel alongside of the suction hose. The pumping engine consisted of a single acting 5 x 8 duplex pump, and was operated at a speed of 100 r. p. m. at the time of inspection. The amount of chlorine being used had been one pound per day, as indicated by the loss in weight of the chlorine cylinder. The day previous to the inspection, however, 8 pounds had been used by the operator in charge. Without a doubt, however, a great deal of this 8 pounds had been wasted by the loss in the air. On the basis of a pound of gas per day and with the above rate of pumping, the rate of application of chlorine was approximately 0.2 parts per million, and at the time of the inspection no color was obtained by means of the starch iodide test. The rate of application of chlorine was increased by opening the control valve on the chlorine cylinder until a blue color was obtained.

Material and instructions were left with the operator for making the starch iodide test, in order that he might make frequent tests and regulate the amount of chlorine being applied at all times in accordance with the results of these tests. Later samples of raw water and treated water were collected at various points in the village.

The watershed tributary to the main supply has an area of approximately one-half square mile. There are said to be two families living on the watershed, but the houses are located well back from the stream. Some 14 acres of land in the immediate vicinity of the reservoir is owned by the village and enclosed by a substantially constructed fence. No insanitary conditions were observed within the enclosure. Above the land owned by the village, however, is pasture land on which cattle and livestock have free access to the stream tributary to the supply. At the time of the inspection, on October 19, the level of the water in the reservoir had risen somewhat, due to the recent rains, and it was thought unlikely that it would be necessary to again resort to pumping from the Forestport feeder, although the fire engine which had been borrowed from the city of Utica was still kept in the village for emergency use.

From our recent inspection it appears that the board of water commissioners has carried out the previous recommendations of this Department with respect to the installation of meters, and are at the present time still engaged in the installation of meters, in order that all services may be metered.

At the time of the inspection the plant of the Rogers Milk Corporation was inspected, where it was found that the discharge of the pump said to deliver water to the overhead tank from the feeder was cross-connected with the village supply and separated only by gate valves. The employees at the factory stated that the meter was provided with check valves, which would prevent the polluted water pumped from the feeder from entering the distribution mains by backward flow through the meter and that, furthermore, the village pressure at this point was above that maintained at the pump, since the water is pumped through an overhead open discharge into the tank and cannot build up any considerable pressure. If, however, the village pressure should for any reason be materially reduced and the gate valve should be left open, it would appear there might be some possibility of polluted water getting back through the meter into the distribution mains.

In a report on an inspection of the supply dated December 28, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply continue the careful supervision of the supply and the installation of meters on all services by which to control, as far as possible, the use of water in the village, and lessen the likelihood of any future shortage.

2. That the authorities continue the installation of the chlorination plant to sterilize the regular supply, in order that the water delivered to the consumers may be of a safe and satisfactory sanitary quality at all times.

3. That the authorities in charge of the water supply engage the services of a competent engineer to aid and advise them as to the best sources and most economical method of developing a new additional source of supply.

4. That the authorities in charge of the public water supply make a detailed investigation of the cross-connection at the Rogers Milk Corporation between the village water main and the discharge of the pump used for delivering the polluted feeder water, in order to ascertain of any likelihood of such polluted feeder water entering the distribution mains at this point, and if so to either sever this connection or provide double check valves in the line in accordance with the plans shown in the blue print accompanying the report.

BRIDGEHAMPTON

A reinspection of the public water supply of the unincorporated village of Bridgehampton, Suffolk county, N. Y. was made by Mr. Alfred Mullikin of this Division on August 8, 1921. Previous inspections of this supply have been made by us in the years 1915 and 1920 and the reports thereon published in the Annual Reports of the Department for these years.

Bridgehampton has a permanent population estimated at 1,400 all of which are served with water from the public water supply. It is located in the town of Southampton about 97 miles from New York city. The waterworks are owned and operated by J. A. Sanford & Sons, Inc., of which Mr. J. A. Sanford is president. The water supply is derived from 3 driven wells, located in a thickly populated section of the village about 2,000 feet south of the railroad station. From the wells the water is pumped into steel tanks under air pressure from which it is forced through the distributing system. The average daily water consumption could not be obtained at the time but figured on a per capita consumption of 80 gallons, would amount to approximately 112,000 gallons per day. In general the details of the waterworks system remain as described in the previous reports, with the exception that about 2,000 feet of 4-inch pipe has been newly laid and a new electric motor installed for automatically operating one of the pumps. Water from this supply is also furnished to the Long Island Railroad at a rate of about 8,000 to 9,000 gallons per day. The railroad company also has a supply of its own located about 300 feet west of the railroad station and about 50 feet north of the railroad tracks. This supply is cross-connected wih the village supply and is provided with one check valve. The Water Company wells are located in the basement of a brick building owned by the Company and consist of two 6-inch driven wells 75 and 85 feet deep respectively, and one 3-inch driven well 315 feet deep. The top of these wells terminate in the bottom of a brick pit, 16 feet below the ground surface. The bottom of the pit is of concrete over which there was about a foot of water. This water accumulates from leakage from the pumps and from two spiggots connected on the discharge line which, when used, drain directly into the pit. The accumulated water is occasionally pumped from the pit by a small rotary pump.

The village is not provided with a sewerage system, the houses being served by privies and cesspools. There are about 7 houses in the vicinity of the well, the nearest of which is about 200 feet south of the wells. The location and number of the sources of pollution are detailed in the previous report and are the same as at the time of the last inspection. The railroad supply is about 200 feet northwest of the railroad station on railroad property and consists of a brick well 8 feet in diameter and 20 feet deep. In the bottom of the well is a 2-inch casing which extends down to greater depth. In the well is a vertical piston pump above which extends a vertical connecting rod leading to a windmill supported on a wooden trussel above the well. The curbing of the well extends about 6 inches above the ground. About 100 feet southwest of the well is an earth vault privy used by the railroad employees.

In a report upon the supply dated September 7, 1921 it was recommended:

1. That the authorities in charge of the water supply cooperate with the village officials in carrying out the recommendations of this Department in that all privies within a distance of 500 feet from the wells be provided with watertight containers.

2. That precaution be taken to see that all sources of pollution within the vicinity of the plant be located, if possible, and eliminated.

BUFFALO

As a result of a request received from the Superintendent of Light Houses, requesting the certification of the Buffalo city water supply for drinking and culinary purposes on board the lighthouse tender "Crocus," Mr. Devendorf of this Department visited Buffalo on April 1st. It was learned that the pumpage has been cut down somewhat since our former inspection and the daily pumpage now runs from 100 to 125 million gallons per day. Chlorine was being applied at an average rate of approximately .24 parts per million at the time of the inspection. The condensing towers of the old Electro-Bleach Company's apparatus have been dismantled and instead a water injector has been installed by the Wallace and Tiernan Company and operates under a head of from 4 to 5 pounds. Chlorine is still being applied at the intake and the water used for operating the injector is supplied from an elevated tank. This water is pumped to the tank by means of a small steam pump. Mr. Wagner stated that the injector has been operating very satisfactorily and that they had no trouble, as formerly, due to the overflowing of the old condensing towers.

It is proposed to apply the chlorine near the Porter avenue pumping station. These plans provide for a 6-inch concrete lined well casing sunk from the ground elevation of about 580 to the top of a 9-foot intake tunnel at an elevation of about 519. Inside this 6-inch well casing it is planned to place two 4-inch channels which are joined together by means of ½-inch iron pipes forming a space through which a 1½ inch rubber hose is placed for applying the chlorine. The channels are made up in 10 foot sections with the exception of the bottom section which is 5 feet in length. The splices in the steel work are to allow for removal and a house is to be placed over the well casing and at least 10 feet head room must be allowed for in order to remove the steel sections. The total weight of the 75 feet of diffuser and steel sections will be approximately between 1,800 and 1,900 pounds. A silver diffuser is fastened to the rubber hose and has seven ½-inch outlets which are planned to face down stream. No definite steps have been taken towards installing the new chlorination apparatus at this point.

It was learned at the time of the inspection that the question of the construction of a filtration plant for the purification of the supply is receiving the attention of the city officials.

As a result of the inspection the necessary data was furnished on April 11, 1921 to the Surgeon General of the United States Public Health Service for the certification of the water supply of Buffalo.

CADOSIA

A reinspection of the public water supply of the hamlet of Cadosia in the town of Hancock, Delaware county, N. Y., was made by Mr. W. W. Young of this Division on October 27, 1921. A previous inspection of the supply was made in 1920 and a report thereon published in the Annual Report for that year.

Cadosia is located on Hawk creek at its junction with the Delaware river at a point near the village of Hancock and has a population of about 150 beside which there is a population of about 100 persons grouped around a nearby acid factory. There are two principal sources of water supply used by about 110 of the people in the hamlet, and two other sources used by the railroad. Aside from this most of the people use private wells. The supply for the hamlet is owned and operated by Mr. William F. Penny and Mr. Barber Forester. The consumption is estimated at about 5,000 gallons a day. The water from the principal one of the two springs supplying the hamlet is obtained by gravity from a covered reservoir located on the lower side of a diverting dam across a ravine. The ravine is situated in a wooded area on an uninhabited slope on the opposite side of the creek from the hamlet. Cattle are free to cross the ravine above the reservoir but due to the topography of the ground and the masonry walls of the reservoir there is little likelihood for pollution of the supply even at times of heavy runoff.

The New York, Ontario and Western Railroad obtain their drinking water from a spring and their water for locomotive and general use from Snake brook at a small dam about three-fourths of a mile above the point where the latter discharges into Hawk creek, about half a mile west of the depot. The intake on the brook supply has recently been moved up stream about one-third mile to a higher elevation and to a point where there is less danger of pollution from the adjacent highway. This little traveled road appears to be the only permanent source of pollution on the watershed of the brook which has an area of approximately one-half a square mile above the reservoir at the point of intake.

The water flows by gravity through an 8-inch main laid along the railroad to two large water tanks for supplying locomotives. One of these tanks is near the point where the Snake brook crosses the railroad, the other is about a half-mile away and just beyond the railroad passenger depot. At the point where this main passes between the depot and railroad restaurant, a tap is reported to be taken off for use in the latter.

The taps in the railroad depot are supplied by gravity through a 1½-inch pipe line from a covered spring near the top of the bank of the deep cut opposite the depot. This spring is small and not easily accessible. It lies at the foot of an uninhabited and forested side hill. Three properties in the hamlet and a yard hydrant between the depot and the water tank are also said to be connected with the pipe line from the spring.

In a report upon the supply dated December 22, 1921, the following conclusions were drawn:

1. That although the necessity for carrying out the recommendations of the previous report still exists, those recommendations have not been carried out.
2. That the water from the east spring, supplying about 35 persons in the hamlet, shows fecal contamination and is subject to pollution from surface wash.
3. That while the sanitary surroundings of the brook supply have been improved, there remain certain opportunities for serious and potentially dangerous contamination of this supply.

It was therefore recommended:

1. That the owners of the supply from the east spring raise the curbing of this spring above the level of the surrounding ground, provide drainage ditches to divert surface wash and fence and post the area surrounding the spring to prevent trespassing in the vicinity.
2. That the proprietors or lessors of the restaurant either use water from the railroad spring or provide other satisfactory supply or purification of all water used from Snake brook.
3. That the New York, Ontario and Western Railroad Company maintain their spring supply in a satisfactory sanitary condition at all times.

CAIRO

A reinspection of the public water supply of the unincorporated village of Cairo was made by Mr. W. C. Emigh, assistant engineer in this Department, on April 2, 1921.

A previous inspection of the supply was made by this Division on July 7, 1908 and a report thereon published in the Annual Report of the Department for the year 1909.

Cairo, a village with a resident population estimated at 500 persons, is located in Greene county. It is well known as a summer resort and during the summer season the population is estimated to average 1,000 persons. The waterworks are owned and operated by a water company of which Mr. Clarence E. Bloodgood is president.

The water supply is derived from an impounding reservoir located one mile west of the village. The water reaches the reservoir from a number of springs and from a small stream which is a tributary of Catskill creek. During a portion of the year, said to average about eight months, water from the former source is used exclusively. During the remaining portion of the year water from the stream is admitted to the reservoir. From the reservoir water is delivered by gravity through the distribution system.

The water company controls only a narrow strip of land around the reservoir which has been partially fenced. The land beyond the fence and on the upper side of the reservoir, draining directly into it, is unprotected and subject to pollution by those conducting farming operations and by trespassers.

The brook which furnishes an auxiliary supply has a watershed above the reservoir of approximately 2 square miles. A few hundred feet upstream from the reservoir intake is located a barn and hog yard in close proximity to the stream. At the farm owned by Mr. A. Millett about one-half mile from the reservoir is a hog yard within 5 feet of the small stream tributary to the reservoir. This stream also passes through the yard of the farm where a small pond has been formed. Barn manure is piled within 40 feet of the stream and at the time of the inspection it was noted that leachings from manure piles had pooled within a few feet of the stream and on land draining directly into it. A privy without vault or container is located within 50 feet of the stream, the drainage of which is toward the stream. The soil in this vicinity is said to be clay. On the farm of A. C. Groat, the farm house is located at a distance of 40 feet from the stream and the privy at a distance of 150 feet. Surface runoff from the vicinity of the barn and barnyard reaches the stream quickly.

In a report dated May 4, 1921, the following recommendations were made:

1. That new sources of water supply not subject to pollution be developed; that, thereafter, water from the present surface auxiliary supply be excluded from the reservoir, and that the present connection between the reservoir and the stream be removed.
2. That sufficient additional land be purchased by the Water Company to include the present sources of spring supply and the land which drains most directly into the reservoir and that this property be surrounded by a substantial fence.
3. Until compliance may be effected with recommendations 1 and 2:
   (a) That, as far as possible, all sources of direct pollution of the water of the auxiliary supply be removed and that measures be taken to guard against a recurrence of same or the establishment of additional sources of pollution.
   (b) That, in case the Water Company experiences difficulty in effectually removing sources of pollution of the auxiliary supply, they apply to this Department for the enactment of rules and regulations in accordance with section 70 of the Public Health Law.
   (c) That a lock be provided for the valve which now controls admission of surface water into the reservoir and that this valve be locked at all times when it is not necessary to admit water to the stream.

CANASERAGA

A reinspection of the public water supply of the village of Canaseraga, Allegany county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department on April 21, 1921. A previous inspection of the supply was made by this Division in 1916 and the report thereon published in the Annual Report of the Department for the year 1917.

Canaseraga is located about 15 miles northwest of the city of Hornell. The present population is estimated at 800, about 90 per cent of which is served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners of which Mr. Oscar I. Shay is president and Mr. B. J. Bennett is superintendent.

The water supply is derived from 12 springs located two miles north of the village in swampy ground at the foot of a hill. From the springs the water flows by gravity to a storage reservoir and thence to the village.

Many of the springs are not properly developed and some of the covers were in a poor condition. The springs are not fenced to prevent cattle from entering the area around them. Surface streams flow to one of the springs and it is probable that surface wash at times enters other springs.

In a report dated June 13, 1921, it was recommended:

1. That steps be taken to protect the springs from contamination by providing proper covers, a diverting ditch and such other improvements as may be found necessary.
2. That the springs be surrounded with a wire fence to keep cattle at least 50 feet from them.

CAPE VINCENT

A reinspection of the public water supply of the village of Cape Vincent, Jefferson county, N. Y. was made by Mr. N. H. Baier, sanitary inspector in this Department on April 14, 1921. Previous inspections of this supply were made by this Division in 1909 and 1918 and the reports thereon are published in the 30th and 40th Annual Reports of the Department respectively.

Cape Vincent is located on the St. Lawrence river about 25 miles west of the city of Watertown. The present population is 1,100, practically all of whom are served by the public water supply. The waterworks are owned by the village and are under the control of a board of water commissioners, of which Mr. Aaron Seeter is president and Mr. E. B. Seebert is superintendent. The water supply is derived from the St. Lawrence river and pumped directly into the mains, the surplus over the consumption flowing into an open steel standpipe.

The seriously polluted condition of the St. Lawrence river has been pointed out to the village authorities in the past and they have been urged to properly filter and chlorinate the supply before it is delivered to the consumers. At the time of the last investigation it was learned that no action has been taken by the village authorities to carry out our recommendations, although the need for them is still urgent.

In the report dated April 25, 1921 the following conclusions were drawn:

1. That the public water supply of the village of Cape Vincent is unsafe for human consumption.
2. That our recommendations relative to the sterilization of the supply have not been carried out.

It was therefore recommended:

1. That the authorities in charge of the public water supply take immediate steps to install a chlorination plant.
2. That chlorine be applied only to the water in sufficient quantity to effectively sterilize it and that frequent tests be made of the chlorinated water for excess chlorine and the rate of chlorine regulated in accordance with these tests.

CATSKILL

A reinspection of the public water supply of the village of Catskill was made by Mr. Emigh, assistant engineer in this Department, on April 4, 1921. Previous inspections of this supply were made by this Division in 1913 and 1918, and reports thereon published in the Annual Reports of the Department for those years.

Catskill, a village with a population of 5,371, is located in Greene county on the west bank of the Hudson river about 32 miles south of Albany. Practically all of the population are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners of which Mr. P. G. Coffin is president.

The water supply is derived from the Hudson river, is chlorinated and is pumped into a reservoir located on high ground within the village limits. From the reservoir the water is delivered by gravity through the distributing system. The average daily consumption for the year ending March 1, 1921, was 888,324 gallons representing a daily per capita consumption of 165 gallons computed on the basis of the population reported in the 1915 census. In general the details of the waterworks system remain as described in previous reports.

Apparatus for the application of hypochlorite of lime as a disinfectant is installed in a room adjoining the pump room. The hypochlorite solution is applied in the suction of the pump. The apparatus is in duplicate and each unit consists of a mixing tank, a solution tank, an air tank, an orifice tank and excessory piping. The hypochlorite is made up into a heavy milk in an iron barrel. From there it is dipped in a pail into the mixing tank which is of wood. In the mixing tank, which is provided with an agitator, the milk is diluted and a solution of hypochlorite formed. From the mixing tank it is discharged by the opening of a valve into the solution tank. The application of the solution to the water supply is dependent upon the flow of water from an orifice tank. The level in the orifice tank is controlled by an adjustable overflow. The water passing out of the orifice tank through the orifice is piped to an air tank the top of which is connected by piping to the solution tank. As the orifice tank is elevated above the solution tank the water passing into the air tank displaces the air in the tank and forces it through the air piping to the top of the solution tank where it, in turn, forces the solution out of the tank. The outlet of the solution tank is in the bottom but rises to an elevation above the top of the tank and leads to the point at which the hypochlorite solution is introduced into the water supply.

The waterworks superintendent, who accompanied our engineer, informed him that 100 pounds of hypochlorite is used per 96-hour week of pumping. On the basis of the daily average consumption a rate of application of 1.94 parts of hypochlorite per million parts of water is indicated. The superintendent stated that it was not customary to make tests of the available chlorine in the hypochlorite purchased, nor to specify the quality to be furnished. In view of this condition it is impossible to determine from data at hand the rate of application of chlorine. A good commercial quality of hypochlorite may be expected to contain 30 per cent of available chlorine in which case the application of chlorine in this instance would be 0.58 parts per million. There is, however, no assurance that the hypochlorite is of such quality and the actual available chlorine may be considerably less. In order that effective disinfection may be obtained at all times all hypochlorite should be purchased under specifications calling for at least 30 per cent available chlorine, and sufficient tests should be made to afford a fair assurance that such quality of hypochlorite is delivered. In addition the treated water should be tested daily for excess chlorine in accordance with the instructions issued by this Department and in order to assure disinfection an excess should be maintained at all times.

The watershed tributary to the supply is approximately 9,300 square miles and the supply is subject to direct pollution from approximately 500,000 people and to indirect pollution from about 600,000 people. It is obvious, therefore, that the water is at all times grossly polluted and generally infected. This conclusion is verified by the records of typhoid fever cases and deaths in the village of Catskill, as compared with the rates in New York State. Records indicate that the Catskill rate has at all times been above the average rate throughout the State. Although, subsequent to the installation of the hypochlorite apparatus in January, 1914, there has been a marked decrease in the typhoid rate in the village, it is to be noted that it continues considerably higher than the state rate. Investigations have been made of the persistence of typhoid in the village, and in general it appears that the water supply has been the primary and most frequent cause. This condition emphasizes the necessity of effective disinfection, as long as the river supply is used, and points to the desirability of the filtration of the present supply, or to the acquisition of a new supply of higher quality.

A considerable number of village residents, estimated at about 10 per cent of the total population, obtain drinking water from a spring supply. The spring is privately owned, but a nominal sum is paid by the village annually to the owner for the use of the water therefrom. The spring is located in a vacant lot bounded by High street, Walnut avenue and Cedar street. It is at a distance of 1,100 feet from the distributing reservoir of the river supply, and at an elevation about 80 feet lower than that of the water surface in the reservoir. It has been developed by the construction of a concrete chamber with a concrete floor and a plastered brick arched roof. Access is afforded by a manhole in the top of the roof, which is protected by a heavy wooden cover secured by bolts. The chamber is well designed and constructed, and appeared to be subject to no permanent sources of direct pollution. The water is piped to 3 drinking fountains, 2 of which are located on the main street of the village, and is also said to be piped to the village school building. The street drinking fountains are fitted with both faucets and nozzles. The nozzles produce vertical jets only about ½ inch in height and not sufficient to assure a reasonable protection of the fixtures from the lips of the drinkers.

In a report on an inspection of the supply dated April 20, 1921, the following recommendations were made:

1. That a suitable treatment plant for the purification of water from the present source of supply be installed and placed in operation at the earliest possible date, or that a new source of supply of satisfactory quality be developed.
2. That, pending the construction and completion of a treatment plant or a new supply as recommended above, every precaution be observed to so operate the present equipment as to reduce the danger of water-borne disease to a minimum.
    (a) That the application of chlorine be continued and the rate of application be controlled by testing the treated water daily in accordance with the instructions of this Department for excess chlorine and by maintaining an excess in the treated water in order to assure adequate disinfection.
    (b) That in the purchase of hypochlorite an available chlorine content of 30 per cent be specified, and that analyses be made of each shipment of hypochlorite received at the plant in order to determine the quantity of available chlorine actually present.
3. That fixtures be provided for the existing street drinking fountains, which will throw a jet of water to a height of at least one inch above the nozzle.

A later inspection of the water supply of Catskill was made on September 8, 1921, at which time it was learned that a new intake chamber had been constructed and that an apparatus for the application of liquid chlorine to the raw water had been installed, and that the old apparatus for sterilizing the supply with hypochlorite of lime had been dismantled.

The new intake chamber is constructed of concrete 5½ feet square and 12 feet deep, and is provided with two 20-inch sluice gates and inserts for 4-inch mesh vertical screens. The chambers are located on the side of a quay wall about 10 feet below the surface of the ground. The new chlorinators, which are in duplicate, are manual control solution feed types of apparatus, manufactured by Wallace & Tiernan Company. The rate of application of chlorine at the time of the inspection was 5.7 pounds per million gallons, and in making tests for excess chlorine in the water by the starch iodide method it was found necessary to increase this rate to 10 pounds per million gallons before a reaction from the test was obtained.

In a report on the inspection of the supply dated September 27, 1921, the following recommendations were made:

1. That the application of liquid chlorine be applied to the raw water in sufficient quantities to properly sterilize the supply, and that the rate be regulated in accordance with the results of daily tests for excess chlorine in the water made in accordance with the directions furnished by this Department at the time of the inspection.

2. That a careful patrol be made over the watershed of the village spring to detect and eliminate, if possible, all sources of pollution; by surrounding the area of the spring with a fence to prevent animals or human beings from coming in the immediate vicinity of the spring and causing accidental, incidental or wilful pollution of the supply; by constructing ditches to divert surface wash which may enter the supply, and until such analyses show this source of supply to be free from active contamination, that its use be abandoned as a drinking supply.

CENTRAL VALLEY

A reinspection of the sanitary condition of the public water supply of the villages of Central Valley and Highland Mills was made by Mr. W. J. Erickson, sanitary inspector, on March 16, 1921. Previous inspections were made of this supply in 1911 and 1915, reports upon which are published in the Annual Reports of this Department for the respective years.

The two unincorporated villages, Central Valley and Highland Mills, have each a population of about 590. They are located in the eastern part of Orange county, about 15 miles southwest of Newburgh. These villages are not provided with public sewer systems. Practically the entire population of the two villages is served by the public water supply which is owned by the Commonwealth Water Company, of which Mr. W. M. Imbrie is president. The supply is regularly derived from Cromwell lake, located about two miles west of Highland Mills. It flows by gravity from the lake to a slow sand filter, from which it continues to the village. There is no method of determining the daily consumption. At times the supply is augmented by using the water from an artificial pond known as Earls pond. The water from this pond is supplied to the Erie railroad for filling locomotive tanks and is seldom supplied to the consumers on account of the stagnant condition of the pond during the summer months.

The filter consists of a concrete tank, 80 by 100 feet in plan and 20 feet deep. It is subdivided and the valves so arranged that either or both sections of the filter may be put into operation. The filtering medium consists of about 2½ feet of sand over a layer of gravel. The filtered water is collected by means of tile underdrains, which conduct it to the effluent main emptying into a clear water basin 15 feet by 40 feet in plan, from which it passed to the distribution system. About 10 feet head is maintained over the filtering medium. The filter is cleaned by scraping the top layer of sand. During the winter months the filter is not used, as the watershed is then practically unoccupied. The filter was not in operation at the time of the inspection, but it was said that it would be put in operation as soon as it had been cleaned. Since the water is at all times subject to accidental pollution, it is important that the filter be operated continuously, being covered, if necessary, to prevent freezing in winter.

Cromwell lake is protected by rules and regulations enacted by this Department and these rules are rigidly enforced. There are but six houses on the watershed, with a permanent population of 6. In summer, however, this is increased to about 150, due to the influx of summer boarders. The cesspools of these places, with one exception, are tight and kept in a sanitary condition. Inspections to determine violations of the rules and regulations are made regularly. Ice cutting is carried on under the supervision of an inspector from the water company. Signs have been posted warning visitors against contaminating the supply.

One source of pollution is the overflow of the cesspool of the Cromwell Lake House, which has a summer population of about 125. This cesspool is located about 450 feet from and 50 feet higher than the lake. It is said that the condition of this cesspool is very objectionable during the summer and frequently clogs and overflows. This overflow could be traced for a considerable distance below the cesspool. It would seem advisable that the proprietor construct a new disposal plant of adequate capacity and constructed on the side of the divide away from the lake. This would not only protect the public water supply, but would also rid the vicinity of the disagreeable odors which must arise from the present inadequate means of disposal.

Earls pond is developed by the construction of a masonry dam across a brook flowing down from Schunemunk mountain. The pond so formed is about 500 feet wide, 1,500 feet long and 6 feet deep. The area tributary to the pond is about half a square mile and is occupied by only one farm, with a total population of 3. The wash from the road leading to the farm is diverted to a point below the reservoir by a ditch. The water from this source is seldom supplied to the consumers on account of the fact that it becomes very stagnant during the summer months.

In a report upon an inspection of the supply dated April 8, 1921, the following conclusions were drawn:

1. That the regular supply derived from Cromwell lake is, during the winter months, when the watershed is practically uninhabited, of fairly satisfactory sanitary quality, though the influx of pleasure seekers during the summer months renders it unfit for human consumption in its raw state.
2. That the efficiency of the filter has not been fully determined.
3. That the supply derived from Earls pond is of satisfactory sanitary quality, though it is depreciated physically due to the development of algæ growths.

It was therefore recommended:

1. That the water company continue its careful supervision of the watershed and rigid enforcement of the rules and regulations.
2. That the filter be used at all times and that an engineer be employed to study the efficiency of the plant and to advise them as to the most practical means of making the method of treatment effective.
3. That, if found necessary, the filtration be supplemented by sterilization with liquid chlorine.
4. That they continue the use of copper sulphate in order to control the growth of algæ.
5. That, in order to improve the physical quality of Earls pond, the reservoir bottom be stripped and the water be regularly treated with copper sulphate in order to prevent the growth of algæ and miscroscopic organisms.

CHATHAM

A reinspection of the public water supply of the village of Chatham was made by Mr. W. J. Erickson, sanitary inspector in this Department, on December 2, 1920. Previous inspections were made by this Department in 1911, 1918 and 1920.

Chatham, which is an incorporated village of about 2,700 inhabitants, is located in the north central part of Columbia county, 22 miles southeast of

Albany on the Boston & Albany railroad. There are no public sewers in the village, privies and cesspools being in general use. The public water supply is owned by the village and is operated under a board of trustees of which Mr. W. P. Pratt is president.

The water supply is derived from the Palmer dug well, located in the western part of the village. The water is pumped from the well into the distribution system. The average daily consumption is about 400,000 gallons, of which the railroads use about half. The regular supply is supplemented by pumping from 20 driven wells, known as the Blinn wells, located in the southern part of the village. The Palmer well is located between the Boston & Albany railroad tracks and Smith's pond. A cesspool located 300 feet from and at a higher elevation than the well appeared to be in a satisfactory condition at the time of the inspection.

The Blinn well supply consists of twenty 2-inch driven wells arranged in pairs averaging 32 feet in depth. A valve pit is provided for each pair of wells, each pair being connected to a 10-inch suction main.

In a report dated January 13, 1921, the following recommendations were made:

1. That in order to safeguard the sanitary quality of the public water supply the village install a comprehensive sanitary sewer system as soon as possible and cesspools, privies and other sources of contamination in the vicinity of the wells be removed.
2. That the Blinn pumping station be put in a satisfactory operating condition so as to be ready for any emergency.
3. That the authorities continue to maintain the grounds surrounding the wells in a clean and sanitary condition.

CHAUTAUQUA COUNTY TUBERCULOSIS HOSPITAL

An inspection of the condition of the water supply at the Newton Memorial Hospital at Cassadaga, Chautauqua county, N. Y., was made by Mr. Henry Ryon, assistant engineer in this Department, on April 8, 1921.

The Newton Memorial hospital is located on the eastern slope of a hill at a distance of about 2,000 feet west of and 150 feet above the upper Cassadaga lake. The soil on the hillside is a heavy loam with a subsoil of clay underlain by shale. The capacity of the institution is about 82 patients and 28 employees. There were, however, only about 40 persons at the hospital at the time of the inspection.

Plans for water supply and sewage disposal for the hospital were approved by this Department on August 12, 1918. The water supply was, according to these plans, to be obtained from a 6-inch drilled well about 150 feet deep, located on the hill some 300 feet west of the institution, and the sewage was to be disposed of by means of settling tanks and intermittent sand filters.

The well from which the water supply of the hospital was to have been obtained is located about 300 feet west of the institution building. This well was said to be 6 inches in diameter, drilled through about 30 feet of clay and 110 feet of shale rock to a total depth of approximately 140 feet. According to information furnished to this Department this well yielded about 20 gallons per minute on continuous pumping. The territory above the well is entirely unpopulated and there are apparently no permanent sources of pollution upon it.

This well is not being used, a second well having been drilled at approximately the same depth about 175 feet nearer the hospital. So far as can be determined there is no record of the location of the second well having been approved by this Department. From such information as could be obtained it seems that the first well was abandoned because it was thought to be polluted. Attention was called by those in charge of the hospital that running water could be heard in this well. This is undoubtedly due to leakage into the well at a point about 30 feet below the surface where the casing joins the rock or possibly a split in the pipe caused by excessive driving, as suggested by the well digger. This leak provides additional water and there seems to be no reason why this water from the upper strata should be excluded, for, as stated above, there is no apparent source of pollution on the watershed.

The second well is developed in accordance with the plans approved for the first well. These plans provided for a small concrete house about 8 feet square to protect the well and pumping machinery. The basement of the building extends about 5 feet below the surface of the ground, the casing of the well projecting 2 or 3 inches above the floor of this basement. A drain is provided for carrying off any water which may fall upon the floor. This drain was stopped up and there was some 2 inches of water on the floor of the pit, undoubtedly polluted to some extent by men working on the board floor at ground level around the pump. A rise of a fraction of an inch more would have allowed this water to flow into the well. When this condition was brought to the attention of the superintendent of the institution he immediately started excavating the drain in order to repair it or clear it of obstructions.

The yield of the well now in use is insufficient for the needs of the institution, even with its present population of less than one-half of its capacity. The pump is said to have a capacity of 22 gallons per minute but cannot be operated for more than 15 minutes at a time without taking air. A large part of the water obtained from the well is apparently used for cooling the refrigerating apparatus, which uses about 1,500 gallons per hour and is operated at present about 2 hours per day.

It would seem desirable that these wells should be carefully tested for capacity and also for the purpose of determining whether or not they both tap the same water bearing strata. This can probably best be done by temporarily altering the gears of the pump so as to reduce its capacity to the limit of the yield of the well and observing the water elevation in the well for several days during continuous pumping. The elevation in the first well should be observed during this test and a record made of it after the pump has been idle for as long a period as possible and at definite times during the continuous pumping. By this means the influence of the second well on the first may be determined. If the pumping on the second well does not materially influence the level of the water of the first well the first well should also be tested by the installation of a pump and continuous pumping in the same manner as suggested for the second well.

If these wells, as seems possible, from their location and the apparent available watershed, will not yield a sufficient quantity for the needs of the institution, other sources of water supply must of course be considered. It seems possible that a better flow of water might be obtained by sinking a well, preferably a dug well several feet in diameter, in the valley lying southwest of the institution, which valley apparently has a considerable larger watershed than the wells above the institution. If the quantity of water needed is only slightly greater than the yield of the present wells, as determined by test, it might be possible to supplement the supply by water from similar wells drilled near the present ones but at a sufficient distance from them to avoid material interference. The area north of the present wells apparently offers the best location for such additional wells.

It is, of course, possible also to obtain water from Cassadaga lake for use in connection with the refrigerating machine and perhaps for fire protection and some other purposes. This would mean the installation of a dual system with the consequent possibility of water from the wrong system being used for drinking and culinary purposes. Such systems cannot usually be recommended and if installed should be entirely separate and the one carrying water unsuitable for drinking and culinary purposes, as the water from Cassadaga lake would be, arranged so that it would be impossible to obtain water at any point for such purposes. Consideration might also be given to cooling the water from the refrigerating machine and using it over again as is done in some installations. Another possible solution of the problem would be to obtain water from the public supply of the village of Lillydale.

Samples of water for chemical analysis were taken from both wells at the time of the inspection and samples for bacteriological examination were taken from well number 2, the condition of well number 1 precluding the possibility of taking of satisfactory samples for bacteriological examination from that well. The results of the examination of samples by the Division of Laboratories and Research are given in the appended table.

The results of the chemical examination of the samples show nothing to indicate that either well was receiving pollution of a possibly dangerous character. The high turbidity and the high figures for albuminoid ammonia and oxygen consumed given in the results of the analyses of the water from well number 1 are undoubtedly due to the fact that the well is not protected from the entrance of small quantities of vegetables and other organic matter and to the fact that it was necessary to take the sample by lowering a vessel into the well, an unsatisfactory method which undoubtedly scraped some material from the sides of the well and caused it to fall into the water. The considerable variation in the chlorine content and the alkalinity of the waters of the two wells is without doubt due to the fact that they are obtained from different strata for, as pointed out above, a considerable portion of water from well number 1 apparently comes from the upper strata of ground and enters the well about 30 feet below the surface where the casing joins the rock. The high chlorine content is undoubtedly derived from mineral sources as is common in wells in this vicinity and of no sanitary significance. The bacteriological examination of the samples from well number 2 show low bacterial counts and the absence of colon bacilli in all of the inoculations tested, indicating that the water was apparently free from active contamination at the time the samples were taken. Since the two wells are close together and subject to similar conditions, the upper one being if anything less liable to pollution, it seems probable that with proper protection the water from well number 1 will show the same freedom from bacteria as well number 2.

In a report upon an inspection of the supply dated April 14, 1921, the following recommendations were made:

1. That the drain from the pit over the present well be repaired and arranged to keep the pit free from water.
2. That both wells be carefully tested for capacity and interference.
3. That consideration be given to securing an additional source of supply either from additional wells of similar character drilled near the present one, from a dug well in the valley southwest of the institution, from Cassadaga lake or from the water supply of Lillydale and to the conservation of the supply by cooling and using over again the water from the refrigerating machine, observing in all cases the precautions pointed out in the body of the report.

CHERRY VALLEY

An investigation of the public water supply of the village of Cherry Valley, Otsego county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 11, 1921. Previous investigations of this supply were made in 1908 and 1916, and the reports published in the 29th and 38th Annual Reports of the Department, respectively.

Cherry Valley is an incorporated village of some 750 inhabitants located in the northeastern portion of Otsego county. There is no public sewer system in the village and the houses are served by privies and cesspools. The water supply is owned by the village and operated under a board of water commissioners, of which Mr. Seth Pearson is president. The public supply is mainly derived from a small stream impounded in a storage and distributing reservoir located about one mile east of the village center. In addition, a smaller reservoir was constructed to collect the water from a small watershed and from a spring flow. This reservoir serves as an auxiliary source of supply whenever it is necessary to clean the main reservoir, or at times when the main supply is turbid after a heavy rainfall. The water consumption is unknown, but is estimated to be approximately 70,000 gallons per day.

The watershed of the small reservoir consists of some 15 acres of land used entirely for cultivation, and is free from any permanent sources of contamination. The watershed above the main reservoir is approximately 2.4 square miles in area and consists mainly of farming land, on which there are 8 dwellings. At the Yeardon place, however, about 1½ miles above the reservoir, the barn buildings are located close to the stream. The contamination of the supply is from surface wash from barnyards, pastures and cultivated fields. The watershed is protected by rules and regulations enacted by this Department in 1897. About 10 acres of land surrounding the main reservoir are owned by the village and inclosed by a fence. Ice is still cut at the reservoir during the winter time under the supervision of the board of water commissioners. It was stated that there are no other available sources of ice in the vicinity of the village.

The recent inspection disclosed that the conditions existing on the watershed were practically the same as described in the former report. A new spillway, however, has been constructed at the main reservoir. A mineral spring, the flow from which is available to the residents and visitors of the village at a fountain located in the center of the village, is used. The spring itself is located about one-half mile southeast of the village and is apparently free from any opportunities for contamination.

In a report on an inspection of the supply dated June 13, 1921, the following recommendations were made:

1. That, as previously pointed out, the village authorities install and operate some satisfactory means of purification, employing a competent engineer to advise them.
2. That the village authorities in charge of the public water supply rigorously enforce the rules and regulations enacted by this Department for the sanitary protection of the public water supply, in order that no insanitary conditions may be allowed to exist on the watershed.
3. That ice cutting upon the reservoir be abandoned.

CLIFTON SPRINGS

An investigation of the public water supply of the village of Clifton Springs was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 10, 1920. A previous investigation of this supply was made in 1913 and a report thereon may be found on page 443 of the 34th Annual Report of the Department for that year.

Clifton Springs is an incorporated village in the northern part of Ontario county about 10 miles west of Geneva. The population is said to be approximately 1,600 inhabitants, exclusive of guests at the Clifton Springs sanitarium, who number some 250 or 300 persons.

The public water supply is derived from a series of springs located approximately 5 miles south of the village. From the springs the water is carried to two small collecting wells from which it is led to a distributing reservoir located at the top of a hill about one mile south of the village. The public water supply is operated by a board of water commissioners, of which Mr. L. E. Martin is president. There are 12 springs located along the slope on the edge of an old cedar swamp, partly covered with second growth timber. The north spring, or Spring No. 1, consists of four 2-foot vitrified tile sunk in the earth, in which there was approximately 2 feet of water. It is estimated that the flow from this spring was, roughly, about 1,000 gallons per hour. The top of the tile extended some 3 feet above the surface of the ground. The earth surrounding the tile was banked up to prevent any surface wash from entering the springs. The tiles themselves, however, were simply placed on top of one another and no concrete provided to make the joint watertight, thus providing opportunities for any surface wash to enter by filtering through the small amount of earth surrounding them. Spring No. 2 is located about 50 feet south of Spring No. 1 and is constructed in a similar manner. The flow from this spring is estimated at approximately 1,500 gallons per hour. Spring No. 3 is approximately 10 feet in depth, has about 5 feet of water and is located some 75 feet south of Spring No. 2. The flow from Spring No. 3 is estimated at approximately 1,200 gallons per hour. Spring No. 4 is located some 100 feet south of Spring No. 3, is 4 feet in depth and there is approximately 2 feet of water in the spring. The flow from this spring is estimated at 400 gallons per hour. Spring No. 5, which is located about 50 feet south of Spring No. 4, is 4 feet in depth and has 2 feet of water. The flow from this spring, together with that of Spring No. 6, is estimated at 300 gallons per hour. Spring No. 6 is 6 feet in depth and has approximately 3 feet of water. A broken tile was observed in this spring giving an opportunity for pollution to enter. Spring No. 7 is about 50 feet south of Spring No. 6, is 8 feet in depth and has approximately 4 feet of water. The flow from this spring is estimated at 800 gallons per hour. Spring No. 8 and Spring No. 9 are located approximately 30 feet apart and 50 feet south of Spring No. 7. Both Spring No. 8 and Spring No. 9 are about 6 feet in depth and each have approximately 2 feet of water. The flow from the springs is approximately 500 gallons per hour. Seventy-five feet south of Spring No. 7 is Spring No. 10, which is approximately 8 feet in depth and has 4 feet of water. The flow from this spring is estimated at 1,000 gallons per hour. Spring No. 11 is 3 feet in depth and has some 2 feet of water. The flow from this spring is, however, rather small and it would appear that the flow might be augmented if properly developed by sinking the tile at a lower depth. Spring No. 12 is 6 feet in depth and has some 4 feet of water. The flow from this spring could not be estimated and was unknown. The total flow of the springs as gauged by the authorities in charge of the public water supply is therefore about 165,000 gallons per 24 hours or approximately 100 gallons per capita per day.

At the time of the inspection approximately 425 feet of 4-inch cast-iron pipe was being laid to collect the water from Springs Nos. 1, 2 and 4, inclusive, and carry it to a small collecting basin located between Springs Nos. 3 and 4. Spring No. 3 had been developed by the construction of a wooden curb and stones placed in the bottom and around the sides and had been only partially filled in on the bottom surrounding a 2-foot vitrified tile pipe which it is planned to carry up above the surface of the ground and then cover. The flow of Springs Nos. 4 to 12 are led through 4-inch tile drains to a 4-inch cast-iron collecting main leading to the small collecting basin. It is not planned at this time to replace these tile collectors. The engineer was informed at the time of the inspection that the tile underdrains had been originally laid some 23 years ago. The location in which these drains are laid consists of a swampy land. The tile drains already taken up have been found to be almost entirely filled with roots and in many places have been cracked and broken, due to the roots entering the drains thus giving rise to opportunities for the surface wash to enter the public water supply.

In view of this experience and on account of the nature of the soil in which the collecting tiles are laid, the village authorities in charge of the public water supply should replace the present tile collectors at the earliest possible time with cast-iron collectors which will prevent the entrance of surface wash into the public water supply as well as provide additional carrying capacity of the collector lines.

At the time of the inspection the engineer was informed that some 4 additional acres have been purchased from the farmer on the southwest which will afford greater protection from surface wash entering the spring. The total watershed area owned by the village now consists of 12 acres. At the time of the inspection no actual opportunity for direct contamination was noticed in the vicinity of the springs.

In a report upon an inspection of the supply dated January 13, 1921, the following recommendations were made:

1. That, in accordance with the previous recommendations of this Department, the village authorities in charge of the public water supply of Clifton Springs replace the tile underdrains with cast-iron collectors at the earliest possible date in order to exclude the possible entrance of surface wash into the spring flow.

2. That the entire property owned by the village be enclosed in a tight fence and properly posted to prevent trespassing and possible contamination of the public water supply by accidental, incidental or wilful pollution of the water or ground by visitors or trespassers on the watershed.

COHOCTON

A reinspection of the public water supply of the village of Cohocton, Steuben county, N. Y., was made by Mr. Alfred Mullikin assistant engineer in this Department on December 13, 1920. A previous inspection of this supply was made by this Division in 1917 and a report thereon published in the Annual Report of the Department for that year.

Cohocton is located in the northern part of Steuben county about 50 miles south of Rochester. The present population is estimated at 900, practically all of which are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees of which Mr. Fred W. Snyder is president and Mr. Erve Wagner is superintendent.

The water supply is derived from several springs located from 1 to 2 miles west of the village and from three driven wells located near the railroad station in the village. The water from the springs flows by gravity to the village, while the water from the wells is pumped directly into the distribution system.

The three springs which are farthest west of the village are located in a cattle field on which considerable sheep manure exists. The springs are provided with wooden covers and are satisfactorily protected from surface wash. The fourth spring located on the south bank of Reynolds creek is loosely constructed of stone. The spring is provided with a wooden cover but is practically on a level with the stream and is probably flooded during times of high water. The fifth spring is located near a farm house. A manure pile is located within 60 feet of the spring.

There are three driven wells located in a thickly populated section of the village. There are three very insanitary earth vault privies and one horse stable within 200 feet of the wells. There are about 15 buildings within 500 feet of the wells, most of the buildings having earth vault privies.

In the report dated February 10, 1921, it was recommended:

1. That the springs and collecting basins be provided with suitable walls, curbs, embankments and ditches to protect them from surface wash and creek water.

2. That, if it is found impracticable to protect any of the springs from creek water, these springs be abandoned.

3. That the village authorities purchase sufficient land around the springs and collecting basins to properly protect them and that this land be fenced so as to prevent trespassing.

4. That, all privies and cesspools within 300 feet of the wells be made watertight and maintained in a satisfactory sanitary condition.

5. That, if it is found impracticable to free the water from all pollution by carrying out these recommendations, the water be treated with liquid chlorine or a new source of supply developed.

COLONIE (Delaware & Hudson Shops)

A reinspection of the water supply of the Colonie railroad shops of the Delaware and Hudson Company in the town of Colonie, Albany county, N. Y., was made by Mr. A. I. Howd, of this Division, on October 7, 1921, as the result of an outbreak of typhoid fever among the employees of the shops.

The Delaware and Hudson railroad shops are located a short distance southwest of the city of Watervliet, and employ at present about 800 persons from cities in the immediate vicinity. The shops are provided with a water supply derived from four sources, namely: the public water supply of the city of Watervliet, a large dug well, the Hudson river and a bottled water supply. The sewage from the shops is discharged into the sewer system of Watervliet.

The water supply obtained from the city of Watervliet is derived from the Normanskill, about 14 miles west of the city. The supply is subjected to filtration and chlorination before being delivered to the consumers. A city water main passes through the shop yards, and to this main a connection has been made. This water supply is the principal drinking water supply of the shops, is used for filling drinking water tanks on passenger coaches and diners, and in addition is used for supplying water to a number of toilets and for other purposes.

The dug well supply is derived from an open well about 60 feet in diameter and about 40 feet deep. The water from this well when used is pumped into an elevated wooden tank, from which it flows by gravity through a distribution system. The pumps are located in a small shed situated partly over the well. The well is located in a low spot in the southwestern part of the shop yards, and, although the concrete casing of the well extends about 2 feet above the ground, surface water may run down around the casing and through openings into the well. This supply was formerly used for potable purposes and for filling drinking water tanks on coaches and diners. It is now maintained as an emergency source of supply for industrial purposes. The use of the dug well supply for potable purposes was discontinued on or about June 8, 1921, upon the recommendation of this Department.

A third water supply is obtained by pumping from the Hudson river. A pumping station is located at the river, from which the water is pumped into a circular steel storage tank at the shops. The water flows from this tank through a main to the boiler house, where the water is pumped by a booster pump into the mains to provide higher pressure. This supply is used for industrial purposes, for fire protection, to supply taps at wash bowls, and for flushing closets in some of the toilet rooms.

A small section of the shops is furnished with a bottled water supply known as the "Standard Springs Bottled Water," obtained from H. Prediger, Troy, N. Y.

In the basement of the boiler room cross-connections exist between the three main water supplies, namely: the Watervliet supply, the Hudson river supply, and the dug well supply. The 3-inch main of the Hudson river supply runs along the floor of the boiler room. At a certain point on the main a riser is provided, which has a 3-inch gate valve a short distance above the floor. This gate was closed at the time of the inspection. To this riser are connected the dug well supply main and the Watervliet supply main. On the city supply main a 2-inch Globe gate valve is provided, which was closed and sealed at the time of the inspection. A pump is located near the cross-connection by which water from the dug well supply may be pumped into either the city main or the Hudson river main by opening the proper gate. By opening both gates the Hudson river water may discharge or be discharged into the city mains, or vice versa, under certain conditions.

An outbreak of typhoid fever occurred between July 24 and August 14 among employees of the Delaware and Hudson shops living at Green Island, Troy and Watervliet. There were 9 cases among employees working at different points in the shop. Investigation by the sanitary supervisor of the district disclosed the fact that different milk supplies and water supplies were used by the cases at their homes and that the only thing in common use by all was the water supply of the shops.

Samples of water were collected at the time of the inspection and sent to the Division of Laboratories and Research for analysis. The results of the analysis of these samples may be found in the appended table.

The results of the analyses of the sample collected from a tap supplying Watervliet city water in the basement of the boiler room show a water clear, colorless and hard. The figures for albuminoid and oxygen consumed are high and indicate the presence of relatively large amounts of decomposable organic matter. The figures for nitrogen in its other forms are moderate. The total bacterial counts are low, but the presence of organisms of the colon group in all the 10 cc. and 1 cc. volumes tested indicates that the water was actively contaminated and unsafe for human consumption. The results of the analysis of the sample collected from the discharge of the pump at the dug well show a very high figure for chlorine, high total bacterial counts and the presence of B. coli in all 10 cc. volumes tested. These results indicate that this supply was polluted and unsatisfactory for use for potable purposes. The results of the analysis of the sample collected from a tap over a wash bowl in the car department toilet, which tap is supplied by Hudson river water, show a very high total bacterial count and the presence of organisms of the B. coli type in all volumes tested, indicating that the water was seriously polluted. The results of the analysis of the sample collected from a tap used for filling the water tanks on the coaches and diners showed a water clear, colorless and hard. The figures for albuminoid ammonia and oxygen consumed are high and indicate the presence of relatively large amounts of decomposable organic matter. The figures for nitrogen in its other forms are moderate. The total bacterial counts are moderate, but the presence of organisms of the B. coli type in all volumes tested indicate that the water was actively contaminated and unsatisfactory for potable purposes.

As a result of this inspection it appeared that the outbreak of typhoid fever among the employees of the Delaware and Hudson shops at Colonie was probably due to the unsatisfactory condition of the water supply at the shops. It is possible that infection may have occurred from drinking polluted Hudson river water from taps located at various points in the shops, or from drinking city water mixed with polluted Hudson river water which may have entered the city water mains through defective or improperly closed gate valves at the existing cross-connections, or through such valves carelessly or wilfully left open by employees.

In a report upon the inspection dated October 25, 1921, the following recommendations were made:

1. That the Delaware and Hudson Company immediately effect a severance of all connections between mains carrying water for drinking purposes and those carrying polluted water for industrial purposes, or provide properly arranged double check valves, gates and gauges, acceptable to this Department, installed in a suitably constructed manhole located at a convenient and readily accessible point outside of any building and near the municipal main.
2. That furnishing polluted Hudson river water to taps, where it is intended to be used by employees for washing purposes, or where it may be used for drinking purposes, be discontinued.

COOKS FALLS

A reinspection of the public water supply of Cooks Falls was made by Mr. W. J. Erickson, sanitary inspector in this Department, on May 11, 1921. Previous inspections of the supply were made in 1908 and 1916 and reports thereon were published in the Annual Reports of the Department for the respective years.

Cooks Falls is an unincorporated village in the southeastern part of Delaware county about 140 miles northwest of New York city. The village has a population of about 300 in winter and about 600 in summer. The public water supply is owned by Mr. George I. Treyz. There is no public sewer system in the village. The public water supply is derived from two small brooks. The intake of one is located about a mile southeast of the village and the intake of the spring brook supply is about a mile west of the village. The water flows from the southeasterly brook to a storage tank located on the O. & W. railroad which uses the major portion of the water derived from this supply. The excess over the amount used by the railroad is delivered to the village. The water from the spring brook goes direct to the village distribution system.

The brook supplying the railroad has a watershed tributary to the reservoir of about 2 square miles. There are but three occupied houses on the watershed. Two of these are at the upper end of the watershed about 2 miles from the intake and at a considerable distance from the main stream. The farm mentioned in the previous report as belonging to Mr. Stout and located about a mile above the intake is now occupied. A tributary stream passes between the house and barn and drains the barnyard. The sink drain discharges into this stream and a manure pile was located at the barn not over 25 feet from the stream. The privy, which was in a bad condition, is located on the bank of a dry channel leading to the main stream. The spring brook watershed above the point of intake is about half a square mile in area and is entirely uninhabited.

In a report on an inspection of the supply dated June 21, 1921 the following recommendations were made:

1. That the owner of the supply rearrange the cross-connections so as to deliver only the supply from the spring brook to the village for human consumption.
2. That the insanitary conditions on the watershed of the old brook be corrected so as to improve the sanitary quality and that it be delivered for human consumption in case of necessity only.
3. That in view of the fact that it is practically impossible to render a surface supply absolutely safe without purification the owner should consider the development of a new auxiliary supply should there be any need for it.

COOPERSTOWN

A reinspection of the public water supply of the village of Cooperstown, Otsego county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department on June 3, 1921. A previous inspection of the supply was made by this Division in 1916 and the report thereon published in the Annual Report of the Department for that year.

Cooperstown is located at Otsego lake in the central part of New York state. The present population is estimated at 2,720, practically all of which are served with water from the public water supply. The waterworks are owned and operated by the Cooperstown Aqueduct Association under the direction of Mr. Waldo Johnstone, president and superintendent. The water supply is derived from Otsego lake and is sterilized with liquid chlorine before being pumped into the distribution system.

Otsego lake is about 1 mile wide and 8 miles long and is subject to pollution, due to the numerous summer cottages and hamlets and villages on the watershed. The shores are used as pleasure resorts during the summer and ice is cut from the lake in the winter.

The previous recommendations of this Department in regard to providing scales for checking the amount of chlorine applied to the water and in regard to keeping complete daily records of the operation of the chlorination apparatus have been carried out.

In a report dated July 6, 1921 it was recommended that the authorities maintain a careful supervision over the operation of the water plant and that liquid chlorine be applied at all times at such rates as will render the supply free from contamination.

CORTLAND

A reinspection of the public water supply of the city of Cortland, Cortland county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 10, 1920. Previous inspections of the supply were made by this Division in the years 1911 and 1915 and reports published in the Annual Reports of the Department for those years.

Cortland is located on the Tioughnioga river 37 miles south of Syracuse. The present population is 13,292, of whom 98 per cent is served with the public supply. The waterworks are owned by the municipality and are under the control of a water board, of which Mr. M. A. Chase is president. The water is derived from a dug well located within the city limits, near its western boundary, and some 500 feet southeast of Otter creek, a tributary of the west branch of Tioughnioga river. It is delivered by pumping through the distributing system. The total daily water consumption is 1¼ million gallons. The city has a sewerage system, the sewage being discharged without treatment into Tioughnioga river at a point 2 miles below the city.

The well, which is 22 feet in diameter and 18 feet deep, is walled with concrete for its entire depth. At the time of the inspection the surface of the water was 4 feet from the ground surface. The sanitary conditions surrounding the well appeared to be good.

In a report on an inspection of the supply dated January 20, 1921 the following conclusions were made:

1. That the water supply was of a satisfactory sanitary quality at the time of the inspection.
2. That the authorities in charge of the water supply have carried out the previous recommendations of this Department.

It was therefore recommended that the authorities continue maintaining their careful supervision of the public water supply.

CROTON-ON-HUDSON

A reinspection of the public water supply of the village of Croton-on-Hudson, Westchester county, N. Y., was made by Mr. W. W. Young of this Division on October 6, 1921. Previous inspections of this supply have been made in 1915 and 1916 and reports thereon published in the Annual Reports of the Department for those years.

Croton-on-Hudson is located at the confluence of the Croton and Hudson rivers about 35 miles north of New York and has a present population estimated at about 2,300. About 80 per cent of the population are served by the public water supply. The supply is also furnished to a population of about 500 persons in the adjoining hamlet of Harmon. The waterworks are owned and operated by the municipality under the direction of Mr. Frank Altz, superintendent.

The water supply is derived from a dug well in the valley of the Croton river. Duplicate pumps are provided in a nearby pumping station for pumping the water from this well directly to the distribution system and reservoir. The average daily consumption amounts to about 150,000 gallons. A public sewer system was being installed at the time of the inspection. The details of the waterworks system remain as described in the previous reports with two exceptions, the removal of the cattle, houses and privies on the watershed adjoining the river above the well; second, the installation in July, 1921, of auxiliary pumping apparatus.

In a report on an inspection of the supply, dated October 17, 1921, the following conclusions were made:

1. That the village authorities in charge of the public water supply have carried out in part the previous recommendations of this Department and the sources of pollution of the Croton river referred to in previous reports appear to have been practically eliminated.

2. That during freshets the overflow from the present dam as now regulated by the city of New York does not seem to flood the land immediately surrounding or above the well.

3. That at the time of the inspection the public water supply of Croton-on-Hudson was of a fairly satisfactory sanitary quality.

It was recommended:

1. That the property of the village on the island near the well be fenced or the entire island purchased or other measures taken so that all cattle and other animals may be excluded from the area surrounding the well.

2. That the authorities in charge of the public water supply make frequent inspections and endeavor to prevent the pollution of the water of the Croton river between Croton dam and the well.

DELANSON

An investigation of the public water supply of the village of Delanson, Schenectady county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 10, 1921. Previous inspections of this supply were made in 1916 and 1920, reports on which may be found in the respective Annual Reports of the State Department of Health.

Delanson is an incorporated village of some 400 inhabitants and is located in the southwestern part of Schenectady county, some 15 miles south of Schenectady on the Delaware and Hudson Railroad. There is no public sewer system in the village, the houses being served mainly by cesspools and privies. The public water supply is owned and operated by the Duanesburg Water Company, of which Mr. Russell Warren is president. The supply is derived from two small streams tributary to the Normanskill creek, on which two reservoirs have been developed by the construction of dams. The first reservoir is located some 1¼ miles north of the village and the second is located some 4 miles north of the village. The flow from the upper reservoir is led through a pipe line to a stream where it runs through an open channel to a small intake located about 1 mile below. From this point the supply is conveyed through a pipe line to the village distributing system and the overflow is discharged into the lower reservoir. The flow from the lower reservoir also is conveyed to the pipe line leading to the village from the upper intake.

There are about 2⅛ square miles of watershed tributary to the upper reservoir, on which there are also some 10 houses. The watershed area tributary to the distributing reservoir is approximately ¼ of a square mile, on which only one house is located. At the upper reservoir a barn and chicken yard are located on the bank of the reservoir, while the house and privy are located below a drainage ditch so that the drainage is not toward the reservoir. At the time of the inspection it was found that the conditions on the watershed and the reservoir were approximately the same as those having been described in the previous report.

In a report on an inspection of the supply dated June 13, 1921, the following conclusions were made:

1. That, as previously pointed out, the public water supply of the village of Delanson is subject to contamination from the animals and persons living upon the watershed as well as from the accidental, incidental or wilful contamination by hunters, fishermen and trespassers on the watershed.

2. That the physical quality of the supply is somewhat affected at times by rainfall and heavy runoff by the resulting high color and turbidity.

3. That the officials in charge of the water company have not carried out the previous recommendations of this Department by installing a chlorinating plant, relocating the road around the lower reservoir or eliminating the contamination of the supply at the upper reservoir by removing the barn buildings located along the lower shore.

It was, therefore, recommended:

That the water company take immediate steps to carry out the previous recommendations of this Department, namely:

(a) The elimination of sources of contamination at the upper reservoir by removing the barn buildings and chicken house from the lower shore.

(b) The relocation of the road around the lower reservoir.

(c) The installation and effective operation of a chlorination plant for sterilizing the public water supply.

(d) The consideration of the matter of the installation of a modern filter plant in order to guarantee a water that shall be of good physical as well as of a safe sanitary quality at all times.

DELHI

A reinspection of the public water supply of the village of Delhi, was made by Mr. W. J. Erickson, sanitary inspector in this Department, on May 10, 1921. Previous inspections were made in 1908 and 1915 and reported upon in the Annual Reports of the Department for the respective years. Delhi is a village of about 1,800 inhabitants located in the central part of Delaware county on the west branch of the Delaware river. The water supply is owned by the village and operated under the direction of the board of water commissioners for which Mr. H. R. Graham is superintendent. The water supply is derived from Steele brook which is impounded in a reservoir located about a mile northwest of the village. From this reservoir the water is distributed through the distributing system. The consumption averages about 115,000 gallons a day. Rules and regulations were enacted by this Department in 1911.

Steele brook has a watershed area above the reservoir of about 5.7 square miles, on which are about 120 inhabitants. From the recent inspection it appears that the sources of contamination on the watershed have been corrected, but that no steps have been taken toward the installation of a chlorine plant as previously recommended.

In a report on an inspection of the supply dated July 21, 1921, the following recommendations were made:

1. That the board of water commissioners continue to rigidly enforce the rules and regulations, making regular inspections in order to detect any violation of these rules and regulations.
2. That in order to protect the supply at all times from serious intermittent contamination of animal and possible human origin, the authorities consider the advisability of installing a modern purification plant in order to yield a safe water at all times.
3. That pending the installation of complete purification the supply be effectively sterilized with liquid chlorine.

DOLGEVILLE

An investigation of the public water supply of Dolgeville, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on April 22, 1921. Previous investigations have been made by this Department in 1916 and 1918, the reports on which may be found in the Annual Reports of the State Department of Health for the respective years.

Dolgeville is an incorporated village of some 3,500 inhabitants and is located partly in Herkimer and partly in Fulton counties, on East Canada creek, some 8 miles northeast of Little Falls. The village is served with a public sewer system and the sewage is discharged into East Canada creek, after treatment in a sewage disposal plant consisting of settling tanks. The water supply is owned by the village and is operated under the board of trustees, of which Mr. Charles M. Cramer is president. The supply is derived from an impounding reservoir on Cold creek, north of the village. Nearly all of the population is served by the public water supply.

The watershed of Cold creek has an area of about 1½ square miles above the incoming reservoir. A mine was formerly located upon the watershed but has not been operated for some years. The water supply is subject to accidental or wilful contamination from passersby on the highways crossing the watershed, from cattle pasturing thereon and from hunters and fishermen who may visit the watershed. At the time of the inspection, for a distance of approximately 1 mile above the reservoir, evidences of recent teaming along the road paralleling the small stream were observed. Furthermore, evidences of fishermen were found along the banks of the streams and excreta observed along the stream bed.

In a report on an inspection of the supply dated May 11, 1921, the following recommendations were made:

1. That the village authorities continue their careful supervision of the supply, making frequent inspections in order to discover and remove any sources of contamination existing on the watershed.
2. That the rules and regulations enacted by this Department for the sanitary protection of the public water supply be rigorously enforced by the authorities in charge of the supply and that all fishermen and hunters be prohibited from trespassing on the watershed above the intake.
3. That if this is impracticable, the village authorities in charge of the public water supply install and put in operation a chlorination plant for the sterilization of the public water supply.
4. That in case the mine should be operated at any time in the future, the previous recommendations concerning the installation of a purification plant be carried out immediately.

DOWNSVILLE

A reinspection of the public water supply of the village of Downsville was made by Mr. W. J. Erickson on May 11, 1921. A previous inspection of this supply was made in 1915 and is reported upon in the Annual Report of this Department for that year.

Downsville, which is an incorporated village of about 600 inhabitants, is located in the south central part of Delaware county on the east branch of the Delaware river. About half of the population is served by the main supply, which is owned by the Downsville Water Company, for which Mr. C. E. Hulbert is president. Two other small supplies, known as the Smith spring supply and the Holmes spring supply, each serve about 10 or 12 houses. The main supply is derived from a small stream known as Tub Mill brook. The water is conveyed from the intake to a small circular reservoir located about a mile from the village. From this reservoir the water is distributed by gravity. At times of drought it is possible to augment the supply from Willson Hollow brook.

The watershed of Tub Mill brook is about half a square mile in area with a total population of 6. The first farm is about half a mile above the intake and is known as the Tompkins farm. The privy is about 175 feet from the stream but only about 20 feet from a drainage course. It is provided with a movable container but in a bad condition. The house drain had clogged prior to the time of the visit and had been torn up. However, the drain emptied into the same drainage course that passes the privy at a point about 24 feet below and thus empties into the creek. The cellar of the house had been banked with manure. Several springs issue from the ground above, one of which passes through the barnyard, another through the pigpen to the stream. About a quarter of a mile above this place is the farm recently purchased by J. L. Stewart. The house is not occupied at present though cattle were being kept in the barn. Cattle were being pastured along the stream below the farm. A watering trough is located in the brook below the barn. The barn which was full of manure and in a very insanitary condition stands 25 feet from the stream. A manure pile was 50 feet from the stream. The privy which does not appear to have been used for some time is about 75 feet from the stream.

The watershed on the Willson Hollow brook is about 5 square miles in area. There are numerous houses located near the stream.

The Smith supply is derived from three or more springs. From these springs the water is conducted to a small reservoir from which it is distributed to the consumers by gravity. They are located in pasture lands. A small spring-fed stream flowing through a field in which cattle were pastured seeps into the ground a few feet above one of the springs and it is probable that the spring is largely fed from this source. There are several houses above this spring and a privy is about 75 feet above on a natural drainage toward the spring, as is also a pigpen and a hen house.

The Holmes spring is located in an open field.

In a report on an inspection of the supply dated June 11, 1921, the following recommendations were made:

1. That immediate steps be taken to correct the insanitary conditions existing on the watershed which may in any way contaminate the water supply furnished by the Downsville Water Company.

2. That should any difficulty be encountered in correcting these conditions the company apply to this Department for the enactment of rules and regulations for the sanitary protection of the water supply.

3. That as it is impractical to remove all possibility of contamination of the supply, the company adopt some modern methods of purification such as effective filtration or sterilization.

4. That, in view of the fact that the present supply is insufficient at times, the company consider the advisability of developing a new supply of safe sanitary quality and of adequate quantity.

5. That the Smith and Holmes supplies be protected from surface wash and fenced to prohibit trespassing.

6. That the spring supplying the Smith supply, which is nearest the privy and below the small stream, be disconnected from the system and abandoned.

DRYDEN

A reinspection of the public water supply of the village of Dryden, Tompkins county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on May 31, 1921. A previous inspection of the supply was made by this Division in the year 1916 and a report thereon published in the Annual Report of the Department for that year.

Dryden is located 34 miles southeast of the city of Auburn, and 12 miles northeast of Ithaca. The present population is estimated at 750. Of the total population 90 per cent is served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners, of which Mr. A. C. Scott is president. The water supply is derived from three springs located about 2½ miles northeast of the village. From these springs the water flows by gravity into the distributing system. No record is kept of the daily consumption, but based on a capita consumption of 80 gallons per day, it would amount to about 54,000 gallons. The springs from which the supply is derived are developed by the construction of masonry basins which are covered with locked wooden covers. The Scofield spring is about 6 feet square and 3 feet deep. The spring is situated in an open field. Cattle pasture in the vicinity of the spring. The collecting spring is located about 50 feet below a highway and acts as a collecting basin for the other springs. It is about 8 feet square and from 4 to 5 feet deep and is provided with a locked wooden cover. Three overflow 3-inch cast-iron pipes extend 3 or 4 feet from the downstream side of the spring and a considerable amount of water is wasted as the 4-inch discharge pipe from this collecting chamber does not take all of the water. The area on which this spring is located is fenced, but trespassing is possible. The nearest house is about 100 feet distant, and at little higher elevation than the spring basin. From the inspection it appears that no steps have been taken to carry out previous recommendations.

In a report on an inspection of the supply dated June 23, 1921, the following recommendations were made:

1. That the present supply be properly developed free from all sources of pollution and sterilized by the application of liquid chlorine at a rate of not less than .25 p. p. m.

2. That the authorities in charge of the water supply immediately carry out the recommendations of this Department that have not as yet been acted upon.

DUNKIRK

An inspection of the public water supply of Dunkirk was made by Mr. Earl Devendorf on June 7, 1921. The city of Dunkirk is located in the northern part of Chautauqua county on the shore of Lake Erie, some 40 miles southwest of Buffalo. The population is about 18,000, practically all of which is served with the public water supply. The waterworks are in charge of the board of water commissioners, of which Mr. W. O. Peck is superintendent. The water supply is derived from Lake Erie. Besides the pumping equipment, the city operates an electric light station. The average daily consumption in 1920 was approximately 4 million gallons per day, of which it is estimated 1½ million gallons per day is used for industrial purposes. The supply is sterilized by applying liquid chlorine to the suction well through a Wallace & Tiernan Manual Control Solution feed type of chlorinator. Chlorine was being applied to the water at the rate of approximately 0.25 parts per million. It is said that the chlorine is applied continuously, except about 5 minutes every two weeks to change the connections and apply a new cylinder.

It was found upon inspection that the conditions surrounding the supply were practically the same as described in the previous report. The city authorities were, however, engaged in remantling the pumping station and were considering acquiring a new source of supply on the main or east branch of Canadaway creek within the town of Arkwright. The design for the proposed new supply involved the use of water for generation of electric energy from the storage resrvoir, after which the water is discharged into a secondary reservoir from which water will be supplied by gravity to the city. The proposed purification plant consists of a rapid sand filtration plant and possibly sterilization with liquid chlorine.

In a memorandum on an inspection of the supply dated December 31, 1921, the following recommendations were made:

1. That the city authorities consider the treatment of the city sewage and the filtration of the lake supply or the acquiring of a new source of supply that shall be both sufficient in quantity and of a safe sanitary quality at all times.

2. That pending the purification of the present supply or the acquisition of a new source of supply, the city authorities continue their careful supervision of the operation of the chlorination apparatus in order that chlorine may be applied in sufficient quantity to properly sterilize the supply.

3. That the city authorities provide the necessary connections for attaching two cylinders to the chlorination apparatus in order that there may be no interruption in the application of chlorine to the public water supply at times of changing cylinders.

EARLVILLE

A reinspection of the public water supply of the village of Earlville, Madison county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer of this Department on February 23, 1921. Previous inspections of this supply were made by this Division in the years 1908 and 1918 and reports thereon published in the Annual Reports of the Department for those years.

Earlville is located about 35 miles southwest of Utica and has a population of about 900, about 90 per cent of which are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees of which Mr. C. E. Taylor is president and Mr. John Moore, water commissioner. The water supply is derived from an impounding reservoir which is fed by two surface streams and numerous springs. Water is at times pumped directly into the reservoir from a driven well nearby.

The reservoir is located about 3 miles northwest of the village. The watershed above the intake of the reservoir is uninhabited. Signs are posted on each side of the reservoir prohibiting trespassing. Algae growths have occurred in the reservoir at times during the summer. Aside from the possibility of accidental or wilful pollution from trespassers and from natural surface wash there are no other sources of pollution.

In a report on the inspection of the supply dated March 4, 1921, the following recommendations were made:

1. That the village authorities continue to exercise a careful supervision over the sources of the water supply.
2. That a fence be constructed on each side of the reservoir in such a manner as to prevent trespassing near the water.
3. That at such times when the water supply is subject to objectionable tastes and odors, the reservoir be treated with proper amounts of copper sulphate under proper supervision.
4. That, if the village authorities have difficulty in preventing pollution of the watershed and reservoir, they apply to this Department for rules and regulations for the protection from contamination of the supply.

EARLVILLE (Emergency Hypochlorite Installation)

The installation of an emergency hypochlorite sterilization apparatus for the sterilization of an auxiliary water supply for the village of Earlville was made by Mr. A. I. Howd of this Department on September 16, and 17, 1921.

The water supply of Earlville is ordinarily derived from an impounding reservoir on a stream a few miles east of the village. Owing to the very dry summer of the present year, the water in the reservoir greatly diminished in quantity until on September 4, 1921, the supply was entirely exhausted and no provision had been made for obtaining water from another source. The village authorities in charge of the water supply immediately obtained a new pump from the Gould Company at Seneca Falls and had it installed and put in operation on September 8 for the purpose of pumping water into the distribution system from the Chenango river at a point in the western part of the village. The new pump was located in a mill on the bank of the Chenango river near the New York, Ontario and Western Railroad station. The pump is a Gould 7 by 8 triplex, operated at about 65 R. P. M. The pump is belt connected to a Westinghouse constant speed induction motor of 25 horsepower, operating at 1,700 R. P. M. The pump is supposed to have a capacity of 200 gallons per minute. The suction of the pump was placed in a small pocket through which water circulates from the stream.

A platform was constructed over the suction pipe near the pump and a barrel was placed on the platform for the storage of the solution of hypochlorite of lime. A connection was made from a point in the barrel a short distance above the bottom thereof and the suction line of the pump under the barrel. A stop cock was placed in the connection near the barrel for the control of the flow of the hypochlorite solution and a stop was placed in the connection near the suction main.

Since the pump was being operated for only 6 hours a day a solution of hypochlorite of lime was made to be used uniformly during the 6 hours of pumping. About 1⅛ pounds of hypochlorite were used to the barrel of water and the solution applied to approximately 90,000 gallons of water over a period of 6 hours. Assuming about 30 per cent of available chlorine in the hypochlorite, the rate of application was equivalent to about 0.5 parts of free chlorine per million parts of water. The apparatus was tested out in the afternoon of September 16 and put into operation at 7:30 in the morning of September 17. A test for excess chlorine by the starch iodide method was made and a satisfactory reaction obtained showing that the proper amount of hypochlorite was being applied. The operator in charge of the pumping equipment was present during the installation of the apparatus and was instructed in the operation of the apparatus for sterilizing the supply and the manner of making a test to indicate whether or not the proper amount of hypochlorite was being applied.

Samples of the raw and chlorinated water were collected and sent to the Division of Laboratories and Research for examination.

The results of the analysis of the sample of water collected from the stream near the suction pipe indicate a high total bacterial count and the presence or organisms of the B. Coli type in all of the 10 c.c. and 1 c.c. volumes tested, indicating that the water was seriously polluted. A sample of chlorinated water collected during the testing of the apparatus shows a reduction of about 50 per cent in the bacterial count and the elimination of organisims of the B. Coli type in 1 cc. volumes. The sample of chlorinated water collected after the apparatus had been put into operation had a very low bacterial count and organisms of the B. Coli type were absent in all volumes tested, indicating that the chlorination of the supply was very effective.

In a report on the investigation of the supply dated December 30, 1921, it was pointed out that owing to the very dry summer, the regular water supply of the village of Earlville became exhausted and it was necessary to obtain an auxiliary supply. This supply was obtained from the Chenango river which is seriously polluted and pumped into the mains several days before this Department was notified and before an apparatus was installed for sterilizing the supply. As a result, the village experienced a slight outbreak of intestinal disturbances and was fortunate in the prevention of an outbreak of typhoid fever. In view of this experience the village authorities should make provision for the installation of an apparatus for the sterilization of this auxiliary supply.

It was therefore recommended that the village authorities be urged to give immediate attention to the securing of an apparatus to be used for the sterilization of the auxiliary supply wherever it is necessary to pump from the Chenango river.

EAST AURORA

A reinspection of the public water supply of the village of East Aurora, Erie county, New York was made by Mr. Alfred Mullikin, assistant engineer in this Department, on December 14, 1920. A previous inspection of the supply was made by this Division in 1914 and a report thereon published in the Annual Report of the Department for that year.

East Aurora is located about 17 miles southeast of Buffalo. The present population is estimated at 3,700 and of the total population 90 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of the board of trustees of which Mr. Fay Ball is president and Mr. Charles Addington is superintendent.

The water supply is derived from two sources, namely, from several springs located in the southern part of the village on the Casenovia creek and from driven wells located some ¾ of a mile north of the village east of the railroad tracks. From the springs, known as the South street supply, water flows by gravity to a collecting reservoir from which it is pumped into the distributing system. From the driven wells, known as the Pine street supply, the water is pumped directly into the distributing system. A reservoir located in the eastern part of the village takes the surplus and acts as an equalizing reservoir. The average daily water consumption is in the neighborhood of 400,000 gallons or 108 gallons per capita. In general the condition of the waterworks system remains as described in a previous report.

The South street supply consists of 4 springs at the foot of a steep hill, developed by the use of wooden boxes about 1½ feet wide, from 4 to 8 feet long and from 2 to 3 feet deep, sunk about 3 feet below the surface of the ground. The sides of the boxes contain numerous drilled holes by which the water enters. These boxes which incase the springs are badly in need of repair and are not provided with tight wooden covers. Surface ditches filled with loose stone in the vicinity of the boxes are so arranged as to permit the surface ground water to flow into these boxes. On top of the bank from which these springs issue and just east of South street some 200 feet from the springs are numerous houses. There is a sewer in South street from which pollution may find its way into the water bearing strata from which the spring water is obtained. On the west side and lower portion of the bank is a fence but the other sides have not been properly fenced to prevent trespassers and accidental or wilful pollution is possible, since there is a small picnic ground within a few hundred feet of the springs.

The South street reservoir into which the spring supply flows is estimated to have a capacity of 500,000 gallons. The reservoir is not provided with a roof and is made up by earth embankment having sides of rip rap and a bottom of concrete. From the precipitous bank it is very likely that the snow or heavy rain on the east side at times causes surface water to enter the reservoir. It would therefore seem desirable that a ditch be made on the east side of the reservoir embankment to carry off all surface wash. There were no other possible sources of pollution noticed. This reservoir is cleaned yearly. It is inclosed by a wire fence which is, however, open sufficiently at the north end to permit the entrance of animals.

The Pine street supply consists of 17 driven wells located north of the village on about 15 acres of ground on the west edge of a pond. The wells are 3 inches in diameter and from 28 to 30 feet deep. These wells are very close together, driven in a space not over 30 feet square in area. There are no houses within 500 feet of the wells.

In the previous report of this Department certain recommendations were made upon which the village authorities have apparently taken no action.

In a report upon an inspection of the supply dated February 9, 1921, it was recommended that the authorities in charge of the water supply immediately carry out the previous recommendations which have not been acted upon, namely; that the authorities secure an additional supply of satisfactory quality from some other source well removed from possible contamination and the complete abandonment of the South street springs; that pending the acquirement of the new supply, the springs be carefully protected and the boxes repaired and provided with tight covers; that the village authorities secure the services of a competent water supply engineer to advise them on matters pertaining to the proper sources and methods for obtaining a sufficient and satisfactory additional water supply.

EAST RANDOLPH

An investigation of the public water supply of the village of East Randolph, Cattaraugus county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on March 31, 1921. A previous investigation of this supply was made in 1916 and a report thereon may be found in the Annual Report of the State Department of Health for that year.

East Randolph is an incorporated village of some 600 inhabitants located in the southwestern part of Cattaraugus county, about 19 miles east of the city of Jamestown. There is no public sewer system in the village, the houses being served by privies and cesspools. The water supply is owned by the village and is derived from springs, one of which is located about 1¼ miles north of the village and the others, known as the Fishery springs, located about 1½ miles southeast of the village. The water from the first spring flows by gravity to a storage reservoir located near the village and the water from the Fishery springs is pumped by waterpower into the distribution system against a pessure maintained by the village reservoir. Nearly all of the population is served with the public water supply.

The spring north of the village is satisfactorily located and there are no nearby sources of pollution.

The Fishery springs are located at the foot of a steep hill at a point which was formerly used as a fish hatchery. There are numerous springs in the vicinity and the yield is far in excess of the amount of water used by the village. The area surrounding the springs is wooded and there are no nearby permanent sources of contamination. The area of the watershed from which the springs may receive surface wash is approximately 15 acres, of which the village is said to own some 10½ acres. The springs are, for the most part, inadequately protected from surface wash and the entire area is subject to the accidental, incidental or wilful contamination from trespassers. At the time of the inspection a wooden table and seats were observed on the grounds surrounding the spring and it is said that the grounds in the summer time are used to a great extent by picnic parties. This practice should be stopped under all consideration as with the springs wholly unprotected this practice would constitute a serious menace to the purity of the supply. The spring basins should be properly developed and protected from surface wash and the entire area enclosed in a man-tight fence provided with a locked gate and the area should be posted to prevent trespassing.

In a report upon an inspection of the supply dated June 21, 1921, the following recommendations were made:

1. That the village authorities endeavor to maintain the conditions surrounding the springs in such a manner that no pollution of the springs may occur.
2. That the area surrounding the Fishery springs be enclosed in a man-tight fence provided with a locked gate and that the area should be posted against trespassing.
3. That the springs be protected from surface wash by the construction of drainage ditches.

EAST SYRACUSE

A reinspection of the public water supply of East Syracuse, Onondaga county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 14, 1920.

Previous inspections of this supply were made in 1915 and 1918 and the reports thereon published in the Annual Reports of the Department for these years.

East Syracuse is located about 5 miles east of the city of Syracuse. The present population is 4,110, practically all of which is served with the public supply. Part of the unincorporated village of Jamesville, which is located 5 miles south of the village, is also served by this supply. The waterworks are owned by the village and are under the control of the board of water commissioners, of which Mr. Elmer Hart is president and Mr. Palmer Gregg is superintendent.

The water supply is derived from Wright brook at a point about 6 miles south of the village, and from the Leiter springs located south of Wright brook. As an auxiliary supply, water is derived from the Pompey springs which are 9 miles south of the village. The supply is sterilized with liquid chlorine and delivered to the village by gravity.

Wright brook above the intake of the water supply has a drainage area of 1.25 square miles and on the watershed which is pasture and forest land, are located 4 houses whose privies are in such condition that their contents may be easily washed into the stream. At the time of the inspection liquid chlorine was being applied at the rate of 0.12 parts per million, a rate too low to satisfactorily sterilize the supply.

In the report dated February 4, 1921, the following conclusions were drawn:

1. That the village authorities are contemplating the construction of a 10,000,000-gallon reservoir to provide additional storage.
2. That the water supply was not of an entirely satisfactory sanitary quality at the time of the inspection.
3. That the rate of application of chlorine is too low to satisfactorily sterilize the water supply.
4. That the authorities in charge of the water supply have partially carried out the recommendations of this Department.

It was therefore recommended:

1. That the authorities in charge of the public water supply apply chlorine to the water continuously in sufficient quantities to effectively sterilize it and that frequent tests be made of the chlorinated water for excess chlorine and the rate of application of chlorine regulated in accordance with the results of the tests.
2. That the authorities remove all surface pollution on the Wright brook watershed.
3. That should difficulty be experienced in removing the sources of pollution, the authorities in charge of the public water supply apply to this Department for the enactment of rules and regulations for the protection of their supply.
4. That the authorities take the necessary steps in increasing the present water supply either by increasing their storage capacity or by developing a new source of supply.

ELLENVILLE

An investigation of the public water supply of the village of Ellenville, Ulster county, N. Y., was made by a representative of this Division on November 4, 1921. This investigation was made at the request of the village authorities with particular reference to the quality of a proposed additional source of public water supply to be obtained from Lake Maratanza. Previous inspections were made in 1908, 1915, 1916 and 1918 and the reports thereon published in the Annual Reports of the Department for these years.

Ellenville is located 26 miles southwest of Kingston. The village has a present population of about 3,100, practically all of whom are served by the public water supply. The waterworks are in charge of a board of water commissioners, of whom Mr. J. M. Hoornbeck is president.

The public water supply is derived by gravity from two streams known as North and South Gully brooks, having adjoining watersheds of about 2 square miles area each. There is also provision for an emergency chlorinated supply from a large dug well near Sandburg creek in the village. Chlorination is also provided for the supply from South Gully, which supplies a population of about 600 in the easterly portion of the village and is subject to pollution from a summer resort located in the upper part of this gully. The total consumption is estimated at 200,000 gallons per day or 64 gallons per capita per day. In general the details of the waterworks system remain as described in the previous report with the exception that there appears to be a smaller number of inhabitants and occupied residences on the watershed tributary to the South Gully than were noted at the time of the previous inspection.

The recent inspection disclosed the fact that, even with the chlorinated water from the South Gully and the well supply in use, it became necessary to prohibit the use of water in summer for such purposes as washing automobiles and sprinkling. It further appeared that an engineer had been employed by the village and an option obtained on a tract of land of some 700 acres in area, about 5 or 10 per cent of which was occupied by Lake Maratanza and from which it was proposed to obtain an additional supply.

The plateau upon which Lake Maratanza and most of this land are located comprises an area about 2 miles long by ½ mile wide, extending in a northerly and southerly direction along the top of the Shawangunk mountains about 2½ miles southeast of Ellenville. It lies at an elevation of about 1,900 feet above the village and adjoins the watersheds of the North and South gully. There is no permanent population on the plateau. Its soil appears composed very largely of white sand and gravel and is almost entirely forested with evergreen trees. It is surrounded by precipitous slopes and is isolated. The village intends to purchase over 1 square mile of the land, which includes all the shores of the lake and practically all of the adjacent watershed tributary to it makes it appear that, if properly protected from opportunity for contamination, Lake Maratanza should afford a supply of satisfactory sanitary quality.

Since the total volume of annual runoff or stream flow of either the North or South Gully brooks would, if stored, yield an amount of water greatly in excess of the daily consumption now used by the village, it has previously been pointed out that one remedy for the shortage of water supply would be the provision of additional storage facilities.

The availability of Fantine Kill as a possible additional source of supply under certain conditions, was also noted at the time of the investigation. This stream, which enters Sandburg creek near the northerly village line, has a comparatively gently sloping watershed about 3 square miles in area above a point suitable for a gravity intake. The top soil, of sandy gravel and shale, appears largely covered with second-growth timber. Except for about 10 occupied houses, half of which are remotely located from the stream, and a road located at some distance from the stream; this watershed appears to be free from any permanent sources of pollution.

In a report upon an inspection of the supply dated November 21, 1921, the following recommendations were made:

1. That the Board of Water Commissioners continue to make frequent and careful inspections of the watersheds of the North and South Gully brooks as well as the sanitary conditions surrounding the well used as an auxiliary source of supply in order to discover and eliminate any sources of pollution that may be found to exist.
2. That the Board of Water Commissioners continue to treat with liquid chlorine at all times the supply from the South Gully and the well, keep records of the rate of application of chlorine and make daily tests for excess chlorine by means of the starch iodide test, a copy of which is attached hereto.
3. That in view of the complicated hydraulic and sanitary problems involved, the Board of Water Commissioners should retain the services of a competent engineer to make a detailed study of the problem and advise them concerning the most economical and feasible plan to adopt in securing additional storage or the acquisition of an auxiliary source of supply.
4. That before any new source of supply is developed the village authorities should receive the approval of the State Water Power Commission in accordance with the provisions of section 499 of the Laws of 1921.

FAYETTEVILLE

A reinspection of the public water supply of the village of Fayetteville, Onondaga county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 11, 1920.

A previous inspection of the supply was made by this Division in 1916 and the report thereon published in the Annual Report of the Department for that year.

Fayetteville is located on the West Shore railroad, about 10 miles southeast of Syracuse. The present population is 1,789, of which practically all are served by the public water supply. The waterworks are owned and operated by the village under a water board, of which Mr. Charles M. Kessler is president. The water is derived from springs located two miles east of the village. As an auxiliary supply, springs have been developed in the southeastern part of the village.

The water from the springs of the main supply is collected in catch basins of masonry construction covered and well protected from surface wash. The village owns some 30 acres of land about the springs, this land having been reforested with pine, ash and spruce. There are three houses within 400 feet of the auxiliary supply. Surface wash from the highway may reach the supply unless suitable precautions for its exclusion are taken.

In the report dated February 18, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply maintain a careful supervision of the supply and the watershed tributary to it.
2. That the auxiliary spring supply be properly protected from the surface wash from the highways in the vicinity.
3. That all houses within 500 feet of the spring be provided with privies having removable containers and that these containers be kept in satisfactory sanitary condition at all times and that the contents of them be removed at regular intervals and buried at some place remote from the water supply.

FRIENDSHIP

A reinspection of the public water supply of the village of Friendship was made by Mr. W. J. Erickson, sanitary inspector in this Department, on December 15, 1920. A previous inspection of this supply was made in 1917 and it was published in the 38th Annual Report of this Department.

Friendship is an incorporated village of about 1,200 inhabitants, located in the west-central part of Allegany county, about 40 miles west of Hornell. Practically all of the population and about 100 outside of the corporate limits are served by the public water supply, which is owned by the village and operated by a board of water commissioners, for which Mr. T. E. Tefft is chairman. The village is not provided with a sewer system, the houses being served by privies and cesspools.

The supply is derived from 8 springs located about 2 miles southeast of the village, and from a deep well located about 2½ miles southwest of the village. A drilled well and a dug well located in the southern part of the village and a new drilled well near the storage reservoir was retained for emergency purposes.

The six upper springs are located in pastures or cultivated land and are not fenced in, and it is therefore possible that some contamination reaches them from this land by infiltration through the soil. The other two springs are located in a wooded ravine and are subject only to incidental contamination from visitors or animals on the watershed. There are no sources of pollution in the vicinity of the deep well.

The new well for emergency use is located near the reservoir and is driven to a depth of about 260 feet through rock to water bearing sand and is said to be cased to the bottom by an 8-inch casing. The well is located at the edge of the wood near the top of a hill and is not subject to pollution other than that of visitors and animals on the watershed. The dug wells in the southern part of the village are located in a comparatively built-up section. There are about six houses within 500 feet of the wells and within 1,000 feet there are six additional houses. All of these houses are provided with cesspools, at least three of which are within 500 feet of the wells. It seems possible that at times, especially when there is a heavy drain on the wells, that contamination reaches them from the cesspools. It was learned at the time of the inspection that the regular supply has become more and more inadequate for the needs of the village, due to the decreased yield of the spring, and at such time it is necessary to pump from the wells.

In the report dated January 19, 1921, the following recommendations were made:

1. That the springs be protected from contamination from pasture lands by fencing so as to exclude cattle from the immediate vicinity.
2. That the village retain an engineer to study into the problem of the development of a new additional supply and to advise as to the most economical method for the development of such a supply that shall yield an adequate quantity of water of satisfactory quality.
3. That pending the development of the new supply, the wells in the southern part of the village be used only in case of necessity and then only after warning to boil the water has been issued.
4. That upon the development of a new additional supply these wells be abandoned.

FLEISCHMANNS

A reinspection of the public water supply of the village of Fleischmanns was made by Mr. Earl Devendorf, a representative of this Division, on July 6 and 7 and August 24, 1921. A previous investigation of this supply was made in 1915 and a report thereon printed in the Annual Report of the Department for that year.

Fleischmanns is an incorporated village having a resident population of some 700 inhabitants and a summer population estimated at from six to ten thousand. Of the total population some 90 per cent are served with the public water supply. The village is not provided with a sewer system, the houses being served by privies and cesspools. The waterworks are now owned by the village, having been purchased from the Griffin Corners Water Company, and are operated by a board of water commissioners of which Mr. Crosby Kelly is president.

The water supply is derived from springs located about 1 mile southeast of the village from which the water flows into a collecting basin some 3 feet square and thence into the main leading to the village, the excess over consumption discharging into the nearby storage reservoir. The storage reservoir is constructed of concrete and covered with a roof, the lower part of which is constructed of wood and the upper part of 1-inch mesh wire netting. The reservoir is 40 by 60 feet in plan and 10 feet 8 inches in depth, having a capacity of some 190,000 gallons. The conditions surrounding these springs are in general as described in the previous report.

The recent inspection was made due to the fact that the regular supply had become exhausted and that it was necessary to pump water from a spring flow subject to pollution. The Department chlorination apparatus was installed and put in operation on July 7, 1921, when the village authorities first started to pump water from the auxiliary supply. At the time of the inspection it was stated that the spring flow had been gauged and found to be approximately 106,000 gallons per 24 hours. Due, however, to the increase in the summer population and the lessened flow of the springs on account of dry weather period, it was necessary for the village to install a small gasoline operated pump, having a capacity of some 10,000 gallons per 24 hours earlier in the season. It was stated that the water consumption was such that the spring supply, together with the 10,000 gallons per day being pumped by the small pump was running behind some 40,000 gallons per 24 hours, as estimated by the drop in the level of the reservoir. With the estimated spring flow given above the water consumption was on this basis at 130,000 gallons per day when the population was estimated at approximately 3,000, giving a per capita rate of consumption of over 43 gallons per day. The pump being used to pump water from the spring flow consisted of a Gould triplex pump, 6 by 5, which was operated at approximately 64 revolutions per minute by a belt driven gasoline engine, and was therefore delivering approximately 100 gallons per minute. The pump had been erected in a field below the spring flow which was subject to pollution from a house situated above the spring. At this house there was a privy and barn and at the time of the inspection the privy had been removed, the vault cleaned and the contents taken away from the watershed, and it was stated that the village authorities had arranged to install a chemical toilet in such a manner as to preclude the possibility of any pollution of the spring flow. The spring flow is, however, still subject to some opportunity for contamination from surface wash from the highway and the field above and from the barn.

The Department chlorination apparatus was installed on July 7 and the operation explained to a representative of the village. The chlorine was applied at the rate of approximately ¾ of a pound per day or .6 parts per million as estimated on the rated capacity of the pump. The application of chlorine was regulated in accordance with the results of the starch iodide tests which were made every hour by the operator. Later the village authorities ordered a manual control chlorination apparatus from the Wallace & Tiernan Company, and on August 24 when the representative of this Department visited Fleischmanns to procure the Department chlorination apparatus, it was found that the new apparatus had been installed, although the pump was not in operation at that time. It was stated that at the end of the season when it was assured that it would not be necessary to use this supply again the apparatus would be taken down and packed away for future use.

As previously pointed out the main supply is collected from springs through drain tile laid below the surface, which extends in most cases to the source of the springs. One is known as the Dump spring, located just at the edge of the railroad embankment, which crosses a small wooded ravine extending to the side of the mountain, and the other is known as the Rock spring and is located about 150 feet from the railroad and west of the Dump spring. While there are, however, no inhabitants on the watershed tributary to this spring, the spring may receive pollution from the infiltration of ground water from the railroad track above. An auxiliary supply was being obtained at the time of the inspection from the overflow of the spring by pumping into the reservoir. There appeared to be no permanent sources of pollution in the vicinity of the spring.

In a report upon an inspection of the supply dated December 30, 1921, the following recommendations were made:

1. That the village authorities continue to exercise a careful sanitary patrol of the surroundings of the regular spring supply in order that there may be no possible pollution of the spring flow.
2. That if at any time in the future it becomes necessary to again use the water from the auxiliary spring supply, the village authorities should first sterilize the supply by means of liquid chlorine before pumping it into the reservoir and regulate the application of chlorine in accordance with the results of the starch iodide test for excess chlorine, a copy of which is appended.
3. That the village authorities should engage the services of a competent sanitary engineer to aid them in securing and developing in the most economical manner such additional supply of water as may be necessary to furnish the village at all seasons of the year with a supply that shall be both adequate in quantity and of a satisfactory sanitary quality.

FULTONVILLE

A reinspection of the public water supply of the incorporated village of Fultonville was made by Mr. A. I. Howd of this Division on August 25, 1921. Previous inspections of this supply have been made by this Division in 1915 and 1918 and the reports thereon published in the annual reports of the Department for the years 1915 and 1918, respectively.

Fultonville, a village with a population of 869, is located in the north-central part of Montgomery county. Of the total population about 70 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of the board of trustees, of which Mr. R. A. Brace is president.

The water supply of the village is derived from a drilled well located in the northwestern part of the village near the Mohawk river. From the well the water is pumped directly into the mains, the surplus over consumption going to a reservoir located on a hill about one mile south of the village. Another supply known as the Starin supply is derived from springs southeast of the village and serves a small section of the village (about 10 or 15 houses). The water from the springs is collected in a small, covered reservoir from which it flows by gravity directly into the mains. It was learned that the village has made an appropriation for a number of meters, it being intended to eventually meter all the taps. No accurate estimate could be obtained as to the daily water consumption. In general the details of the waterworks system remain as described in the previous reports, but the ownership of the system has since the previous inspection, been transferred from the Fultonville Water Company to the village, the transfer taking place March 1, 1921.

The present investigation was made as a result of a request from the local board of health of the village of Fultonville. It was stated that the regular supply from the drilled well was insufficient to meet the needs of the village, and that the village was planning to pump water from an abandoned well near the pumping station. The abandoned well is a dug well about 20 feet in diameter and 40 to 45 feet deep. From the bottom of the dug well a drilled well is said to extend to an additional depth of 50 feet. The water in the well stood at a depth of about 15 or 20 feet below the surface of the ground. The well is loosely stoned up and is provided with a conical-shaped shingled roof, from which a large number of shingles are missing. The water of the well appeared oily on the surface, which was said to be due to the fact that the water of the well had risen and fallen, causing the water to flow through an old suction pipe into the pump pit where it came in contact with oil which was carried out with the receding of the water. The well is located adjacent to the pumping station, on the edge of a dirt sidewalk and roadway, about 10 feet from a house, within 50 feet of a very insanitary privy and within 200 feet of the Mohawk river. The well has not been used for some eleven years. It was stated by old residents of the village and it was learned from records at the pumping station that when water used to be pumped from the well very often it became quite turbid and, therefore, of an unsatisfactory physical quality. It is evident, therefore, that the well is subject to pollution from a number of sources and should not be considered safe for potable purposes without sterilization. If the sanitary conditions in the vicinity of the well were improved the water of the well might be suitable for domestic use, provided it is sterilized with liquid chlorine at all times, and provided the objectionable physical features of the water are overcome.

The reservoir on the hill south of the village is of masonry construction, about 35 feet wide, 75 feet long and about 8 feet deep. The reservoir is located about 25 feet from and at a slight elevation above a highway. It is not covered. A fence about 20 inches high, formed by laying 2 10-inch planks on their sides. existed at one time on top of the masonry walls of the reservoir, but the fence has gradually broken down so that only a very small part of it remains in position. A relatively large stream of water was coming from the embankment of the reservoir, due to a leak therein. Due to the fact that the village is experiencing a shortage of water the reservoir should be repaired as soon as possible.

Inasmuch as the reservoir is not covered, the waters thereof are subject to pollution from a number of sources. Dirt from the highway nearby was seen to blow into the reservoir at the time of the inspection. Dead field mice and frogs were noticed in the reservoir. The waters are also subject to accidental or wilful pollution from trespassers. It was learned that people living near the reservoir go to the reservoir at times to obtain water. A small growth of algae appeared on the bottom of the reservoir.

Complaints regarding tastes and odors in the public water supply are frequent. It was learned that generally, after the reservoir has been cleaned, the tastes and odors disappear for a time. Covering the reservoir with a tight roof would exclude animals and considerable amounts of foreign matter and prevent to a great extent the growth of algae. The elimination of the above objectionable features should improve the potability of the water.

The Starin supply remains in practically the same conditions as at the time of the previous inspection. Although there were no apparent sources of pollution the springs remain inadequately protected from surface wash.

It was learned that the village authorities have employed a consulting engineer to advise them in regard to their water supply. It appears that none of the other recommendations made in the previous reports of this Department have been carried out.

Samples of water were collected at the time of the inspection and sent to the division of laboratories and research for analysis. The results of the analysis of the sample of water collected from the dug well which it is proposed to use, show a very high bacterial count and the presence of B. coli in all 10 cc. and 1 cc. volumes tested, indicating that the water was seriously polluted.

In a report upon an inspection of the supply, dated September 14, 1921, the following recommendations were made:

1. That the village authorities take immediate steps to remove the privies located near the well from which the public water supply is derived and to satisfactorily clean and sterilize the vaults.
2. That the dug well near the pumping station should not be used as a source of public water supply and that the old connection to the well in the wall of the pumping station should be plugged to prevent water of the well from flowing into the pump pit at time of high water.
3. That the reservoir on the hill south of the village be cleaned and repaired.
4. That the reservoir be provided with a suitable cover and surrounded by a tight fence for the reasons pointed out in the body of this report.
5. That the village secure an additional source of water supply, free from pollution, for emergency use, or preferably, if an adequate and satisfactory new supply can be obtained, it be retained for emergency purposes.

GENEVA

An investigation of the public water supply of the city of Geneva was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 18, 1920. Previous investigations of this supply were made by this Division in 1903, 1909, 1914, 1917 and 1919. Reports on these investigations may be found published in the Annual Reports of the State Department of Health for the respective years.

Geneva is a city of some 15,000 inhabitants, located in the eastern part of Ontario county at the northern end of Seneca lake. The city is served with a system of sewers which discharge into the lake at various points between one and two miles from the water supply intake and toward the outlet of the lake so that there is little likelihood of the water supply being affected from the sewage discharging into the lake. The public water supply is owned and operated by the city under the board of public works, of which Mr. H. K. Seybolt is superintendent.

The supply is obtained by pumping from the lake and filtering through slow sand filters and pumping the filtered water to the storage reservoir from which point it is fed by gravity throughout the city. The intake consists of a crib located some 570 feet from shore in approximately 20 feet of water. The water enters a pump well, after passing through the screen chamber. From the pump well the water is pumped by a low lift centrifugal pump to the filters. There are three units of covered filters having a total area of 0.7 of an acre. After filtration the water enters a clear water basin from which it is pumped to the storage reservoir. There are no cross-connections existing between the public water supply mains and any private fire supplies. The total amount of water pumped for the year ending December 31, 1919, amounted to 134 gallons per capita per day, of which 81½ gallons were measured through the metered services.

During 1917 the first two filter units became inadequate to treat the entire consumption of the city and at times small amounts of raw water were by-passed, which gave rise to several cases of typhoid fever. Pending the construction of the third filter unit and at the request of the local authorities the emergency chlorination plant of the engineering division of this Department was installed and operated. At the time of the inspection the public water supply was found to be in practically the same condition as described in the former report. No action has been taken towards carrying out the recommendation of acquiring a chlorination plant or sterilizing the public water supply as recommended in our last report.

Samples of water are analyzed about once a week by Hill & Ferguson, of New York City, and daily analyses are made by the city bacteriologist, Miss Mildred Davis. The results of these analyses show that while the filters are furnishing a satisfactory degree of purification, there are times when organisms of the *B. coli* type are isolated from the samples of filtered water. It is such results which cause this Department to recommend the installation of a chlorination apparatus in order that the supply may be of unquestioned purity at all times.

The results of analyses of samples of water collected at the time of the inspection indicate a removal of 25 per cent and 17 per cent of the organic matter as measured by the albuminoid ammonia and oxygen consumed contents, respectively, and an average total bacterial removal of 97.7 per cent.

In a report upon an inspection of the supply, dated February 7, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply continue their careful supervision and operation of the filter plant.
2. That, as an additional safeguard of the sanitary quality of the water and as previously recommended, the city install and carefully operate apparatus for the sterilization of the public water supply.

GILBOA

An investigation of the water supply of Gilboa, Schoharie county, N. Y., was made by Mr. William Young of this Department on June 30, 1921. A previous investigation of this water supply was made by this Department on August 5, 1915 and a report thereon may be found on page 409 of the 36th Annual Report of this Department.

At that time the population of the village was estimated at 300 and the water supply, owned by the Gilboa Water Company, obtained from 5 springs and delivered without treatment to the consumers through some 1½ miles of pipe.

Since the time of the last inspection the contractor building the Gilboa dam has purchased the property of the water company. This contractor maintains a camp of between 400 and 500 men in addition to which a considerable number of the original inhabitants still remain in the village, all of whom are using water from the supply. The water is as stated before obtained from 6 springs, 5 of which are connected to the reservoir by a single pipe and the

6th by a separate line. The discharge from the springs appeared at the time of the inspection to be about 20,000 gallons per day. Due to a long drought, water in the 100,000 gallon storage reservoir, connected with the system and normally supplied from the springs, became very low. To keep the reservoir full and ready for use in case of fire the contractor tapped a 10-inch force main which he was using to convey water from the Manorkill to a giant or hydraulic nozzle. The tap is said to be a ½-inch one and is connected by about 100 feet of 1-inch pipe to the reservoir. At the time of the inspection the reservoir was nearly full and the auxiliary supply from the Manorkill had not been used for some time but the piping was so arranged that the water could be used at any time.

An inspection was made of the watershed of the Manorkill above the dam from which the emergency supply is taken. Its area is about 25 square miles. The examination showed it to contain a population of about 400 persons, a considerable portion of whom are residents of West Conesville, Conesville and Manorkill. A close examination revealed the fact that about 15 feet from the stream entering the Manorkill from the north at West Conesville there was a privy in such condition that the contents of its vault might be readily washed into the stream. Four other privies in unsatisfactory conditions were found near the banks of the stream within less than ½ mile above the Manorkill dam. The property at Conesville was relatively free from such conditions but conditions similar to those at West Conesville were found at Manorkill and along the 6 miles or more of road between the dam and Manorkill.

The most dangerous source of contamination observed was at the house of a milliner on the road between West Conesville and Conesville at a point about a mile and a half above the dam. Here the bank is extremely steep and a privy extended out over the rock bed of the stream. Although the stream at the time of the inspection was not flowing across these rocks it undoubtedly does so at times of high water on which occasions the stream would carry away the accumulated deposits.

Beside the form of indirect pollution from human sources, it was stated that the inhabitants along the stream deposit garbage and other wastes in the stream near their residences. Many sources of pollution such as stables, pig pens and chicken yards, are located near the stream and its tributaries and in some cases liquid was flowing directly from manure piles into the creeks. In addition to this and the ordinary contamination due to the agricultural use of the bottom land through the valley there was a creamery above Manorkill discharging whey over a filled up cesspool and ponds directly into the Manorkill.

In a report upon an investigation of the supply dated July 5, 1921, the following conclusions were drawn:

1. That the quantity of water obtainable from the original source, the springs, is not sufficient to meet the present needs of the contractor's camp.
2. That arrangements have been made to take water from the Manorkill to supplement the water from the spring.
3. That the water from this source of auxiliary supply is subject to gross pollution and is not safe for human consumption without purification.
4. That the benefit of storage in the reservoir is not fully utilized since the inlet and outlet are unnecessarily close together.
5. That the hamlet of Gilboa is to be largely submerged on the completion of the dam about 4 years from now so that the development of a permanent source of water supply is not essential, although the development of a temporary supply of adequate quantity and safe quality is necessary.

It was, therefore, recommended:

1. That a new source of supply of adequate quantity and safe quality be developed or the auxiliary supply from the Manorkill be continuously

purified by filtration or chlorination before being discharged into the reservoir or used for domestic purposes.

2. That until a new source of supply has been developed, or the filtration or chlorination plant has been in satisfactory operation for at least one week, the water be boiled before its use for domestic purposes.

GLOVERSVILLE (Municipal Supply)

An investigation of the public water supply of Gloversville, as furnished by the municipal supply was made by Mr. Earl Devendorf, assistant engineer in this Department, on April 21 and May 23, 1921. A previous investigation of this supply was made in 1918 and a report thereon may be found on page 178, Volume 2, of the 19th Annual Report of the State Department of Health. The public water supply is owned by the municipality and is operated under the direction of a board of water commissioners, of which Mr. Arthur Cotton is president. The water supply is derived by impounding surface water from the hills to the north of the city, from which the supply is distributed to the city by gravity. These reservoirs, except for the Middle and Poor House reservoirs, discharge into a pipe line extending from the Dixon reservoir to the city distribution system at the northern boundary of the city. The normal daily consumption is said to vary from 2¼ to 2½ million gallons per day. There are several large mills in the city which use from 900,000 to 1,000,000 gallons per day, when they are operating on full schedule.

The most northerly of the reservoirs is the Cameron pond reservoir, which is used for storage purposes. The water from this reservoir flows through an open stream known as the Jackson-Summit creek to a point below a sparsely settled community known as Jackson Summit, at which point a diverting dam and intake have been constructed. From this intake the water is discharged into the Dixon reservoir and thence to the city. It is connected to Beach creek, Rice creek and Rice creek storage reservoirs. The Poor House and Middle reservoirs are located about 1 mile northwest of the city line. The watershed above the Cameron reservoir is an unpopulated and heavily wooded district. The stream between the Jackson Summit intake and the Cameron reservoir flows through a sparsely settled community on which there are a number of barns and privies, so located that drainage from them may indirectly reach the stream. The Dixon and Beach creek watersheds are wild, wooded and in the case of Dixon creek, uninhabited. The Beach creek watershed has three houses, remotely located from the stream. The watersheds of the Rice and Port creek reservoirs are entirely owned by the city and are fenced and posted against trespassing. The watershed of the Poor House reservoir is owned by the city and enclosed by a tight fence. The Middle reservoir is fed by springs and is fenced to prevent trespassing. Ditches have been dug to divert surface wash from the basin.

The authorities in charge of the public water supply have, in accordance with the previous recommendations of this Department, caused a chlorination plant to be installed for sterilizing the public water supply derived from the Cameron, Beach creek, Dixon, Rice creek reservoirs and Rice creek storage reservoir. The chlorination apparatus consists of a Wallace and Tiernan automatic control, Venturi operated, dry feed chlorinator. The chlorine is applied by means of an injector. Chlorine was being applied to the water at the rate of approximately 2 pounds per million gallons. At the time of the inspection all of the supply used by the city was being treated by this chlorination plant, the Poor House and Middle Spring reservoirs being out of service. The chlorination plant was installed in the summer of 1919. The city authorities have purchased one or two additional pieces of property located along the stream between Cameron reservoir and the Jackson Summit intake. The city is gradually purchasing these habitations and plan eventually to control all of the property adjoining the stream between the Jackson Summit intake and the Cameron reservoir.

There are 4 factories in the city in which auxiliary fire supplies were used in addition to the regular public supply. These mills were the Surpass Leather Company, Lincoln street; the Gloversville Knitting Company, Beaver street; the Parkhurst Woolen Company, Harrison street, and the Gloversville Leather Company, West Fulton street. At the Gloversville Knitting Company on Beaver street it was found that the fire pumps are connected with the Cayadutta creek and springs. The private supply is protected by means of a single check valve and gate valve. At the factory of the Parkhurst Woolen Company on Harrison street the supply for fire purposes is derived from a pond formed by impounding the flow of a small creek draining the southern part of the city. The fire service line is separated from the public mains by three check valves. At the Gloversville Leather Company's factory an auxiliary supply for fire purposes is derived from a small surface stream. The discharge main of the fire pump is separated from the city main by double-check valves.

In a report on an inspection of the supply dated June 21, 1921, the following recommendations were made:

> 1. That the city authorities continue their efforts protecting the quality of the water supply and maintain their policy of improving the conditions upon the various watersheds.
>
> 2. That the city authorities continue to operate the chlorination plant in a continuous and active manner in order that a safe, sanitary water supply may at all times be assured to the inhabitants of the city.
>
> 3. That the city authorities take steps to have the city main entirely disconnected from the mains used for fire purposes at the Gloversville Knitting Company, and all other factories provided with an auxiliary fire supply, or provide such connections with double-check and gate valves in accessible manholes in accordance with the general plans approved by this Department, a blue print of which is attached.

GLOVERSVILLE (Kingsboro Water Company)

An investigation of that portion of the public water supply of Gloversville furnished by the Kingsboro Water Company was made by Mr. Earl Devendorf, assistant engineer in this Department, on April 21, 1921. Gloversville is a city of approximately 23,000 inhabitants, and is located in the central portion of Fulton county, some 8 miles north of Fonda. A previous investigation of this supply was made in 1918 and a report thereon may be found on page 183, Volume 2, of the 1919 Annual Report of the State Department of Health.

The Kingsboro water supply is owned and operated by the Kingsboro Water Company, of which Mr. E. L. Heacock is president. It is estimated that approximately 5 per cent of the population of Gloversville receives water from the Kingsboro supply. The supply is derived from two open, shallow, spring-fed reservoirs. These reservoirs are located at the foot of a high hill and at a distance of approximately 1½ miles northwest of the city. The field above the north reservoir is used for pasture purposes. The field above the south reservoir is, however, owned by the company and has recently been reforested. During the warm months trouble has been experienced from algae growths occurring in these reservoirs and these growths have been removed by skimming.

In a report on an inspection of the supply dated May 12, 1921, the following conclusions were made:

> 1. That the public water supply as furnished by the Kingsboro Water Company is of a fairly satisfactory physical and sanitary quality.
>
> 2. That some slight trouble has been experienced at times due to the growth of algae in the spring-fed reservoirs.

It was, therefore, recommended:

1. That the officials in charge of the Kingsboro Water Company continue careful supervision of the supply to prevent any possible contamination of the supply.
2. That the officials endeavor to eliminate the algae growth by the judicious application of copper sulphate in the proportion of from 1 to 2 pounds per million gallons or approximately 1 ounce to each of the spring-fed reservoirs.

GRANVILLE

A reinspection of the public water supply of the village of Granville was made on April 1, 1921 by Mr. A. I. Howd, assistant engineer in this Department, previous investigations of this supply having been made by the Department in 1912, 1916 and 1917.

The village of Granville is located in the eastern part of Washington county adjacent to the New York–Vermont State line about 70 miles northeast of Albany. The population of the village is about 4,000, practically all of whom are served with water from the public supply. The waterworks are owned and operated by the village under the direction of the board of trustees.

The water supply is derived from the Mattawee river at a point in the eastern part of the village near the state line. The water flows through a pipe line by gravity to a pumping station in the village where it is chlorinated before being delivered to the consumers. The water is pumped directly into the mains, the surplus over consumption going to a storage reservoir from which the supply is drawn when the pumps are not in operation. The water consumption varies from about 400,000 to 500,000 gallons per day. There is no accurate method of obtaining the actual daily water consumption. The present investigation disclosed the fact that most of the recommendations of the previous report have been carried out. The rate of application of the chlorine has been increased and the amount applied is varied according to the pump in use. According to the statements of the attendant at the pumping station, however, the rate of application of the chlorine is not increased at times when the water is turbid.

In regard to the fact brought out in the previous report, that the chlorine apparatus did not operate properly at times of high water, it may be stated that a strainer was put on the feed pipe supplying water to the chlorinator which keeps sediment at times of high water from stopping up the pipes and which was said by the man in charge of the plant to remedy the unsatisfactory conditions.

Daily records are now kept at the pumping station showing the amount of water pumped, time of pumping, weight of chlorine cylinders, amount of chlorine applied and other desirable data. From these records it was learned that on the night of March 21, 1921, a leak developed in the chlorine apparatus around a connection. The flow of chlorine was stopped at 9:10 P. M. and the apparatus was not repaired until about 8 o'clock the following morning. During the time the chlorinator was out of use pumping of water into the mains and reservoir was continuous. It was stated by the attendant that on different occasions it has been necessary to shut off the chlorine apparatus while pumping has been going on. The attendant does not repair the apparatus but has to send for a man, which may account for some delay in repairing.

In a report upon an inspection of the supply dated April 26, 1921, the following recommendations were made:

1. That the village authorities carry out the recommendation of the previous report that has not been carried out, namely: that after rains and at times when the organic content of the water is high the rate of application of the chlorine be increased about 0.20 parts per million.
2. That the village authorities acquire at once apparatus for making the starch iodide or tolidin test for excess chlorine and that the attend-

ant in charge of the plant make daily tests of the treated water to determine whether or not the proper amount of chlorine is being applied to the water, and regulate the rate of application of the chlorine accordingly.

3. That the attendant at the pumping station make frequent and careful inspections of the chlorination apparatus and keep all connections tight so that it will not become necessary to shut down the chlorination apparatus while pumping, and that duplicate parts be kept on hand at all times.

4. That the village authorities have the scales repaired upon which the chlorine cylinder rests so that they will weigh accurately or that they provide new scales.

A reinspection of the public water supply of Granville was made on August 19, 1921, at which time it was learned that the recommendations of this Department in regard to providing new scales for the chlorine cylinders and the recommendation in regard to providing duplicate parts for the chlorination apparatus, have been carried out. No action, however, had been taken by the village authorities to acquire apparatus for making the starch iodide test for excess chlorine. In a letter to the village authorities they were urged to take immediate action to provide the necessary apparatus and make the test for excess chlorine daily in accordance with our recommendations.

GREENPORT

A reinspection of the public water supply of the village of Greenport, Suffolk county, N. Y., was made by Mr. Alfred Mullikin of this Division on August 9, 1921. Previous inspections of this supply have been made in 1916, 1919 and 1920 and the reports thereon published in the Annual Reports of the Department for those years.

Greenport, a village with a population estimated in winter at 3,100 and in summer at 5,000 is located on the main line of the Long Island Railroad about 96 miles east of New York City. Of the total population 80 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners. The water supply is derived from 2 dug wells located ½ mile west of the center of the village and pumped directly into the distribution system. The original supply of 2 dug wells and 8 driven wells has been excluded from the distributing system.

One of the new wells dug in 1919 is located about ¼ mile west of the main pumping plant near Moores' Woods. It is 15 feet in diameter and 30 feet deep, provided with a brick curbing and a flat wooden cover which is kept locked. There are no houses within ¼ of a mile of the well and apparently no sources of pollution.

The other well, dug in 1920, is located about 110 feet west of the main pumping plant. This well is constructed of brick and is 16 feet in diameter and 35 feet deep. The top of the well wall converges to a manhole which extends 3 feet above the ground surface and which is provided with a locked wooden cover. There seems to be no direct source of pollution in the vicinity of the well. An earth vault privy is located about 300 or 400 feet from the well.

The Long Island Railroad has a separate water supply which is used in addition to the village supply on passenger coaches for drinking purposes. This supply is obtained from a dug well located about 700 feet west of the railroad depot and 25 feet south of the railroad tracks. The well is constructed of brick and is about 6 feet in diameter and 20 feet deep. The top of the well is flush with the surface of the ground and is provided with a wooden cover. One earth vault privy is located about 125 feet from the well and the other is located about 200 feet from the well. The water is pumped from the well into a wooden tank having a capacity of about 35,000 gallons from which it is taken for use on the coaches.

The previous recommendations of this Department in regard to protecting the wells from contamination, the raising of the curbing of the old wells and the abandoning of the oil and waste water pit have not been carried out.

In a report dated October 27, 1921, the following conclusions were made:

1. That while the village water supply at the time of the inspection was of a fairly satisfactory sanitary quality it contained a very high chlorine content.
2. That the authorities in charge of the village water supply have not carried out the previous recommendations of this Department as embodied in this report with the exception that a privy at the main pumping plant has been removed.
3. That the 1919 dug well was receiving a slight amount of active contamination at the time the samples were collected.
4. That a privy located some 300 feet southeast of the plant is not provided with watertight containers.
5. That although the Long Island Railroad supply was of a fairly satisfactory sanitary quality at the time of the inspection, it is, as indicated by the analyses, receiving a considerable amount of pollution which, although largely oxidized and rendered harmless at present, may become active and dangerous under certain hydraulic conditions of the ground water, due to seasonal variations or to heavy draughts of the well. The supply is, therefore, to be looked upon with suspicion.

It was therefore recommended:

1. That the municipal authorities in charge of the water supply carry out at once such of our previous recommendations as have not as yet been acted upon.
2. That a careful sanitary patrol be made in the vicinity of the 1919 dug well to ascertain and eliminate the sources of contamination and if this is not possible that the supply be sterilized by the application of liquid chlorine.
3. That the Long Island Railroad Company carefully protect their dug well by raising the curbing a sufficient height above the ground to prevent surface wash entering the well.
4. That the sources of pollution in the vicinity of the railroad well be removed by providing watertight, removable containers for all privies within 300 feet of the well and properly removing and disposing of the contents of these containers at some remote point in a satisfactory manner.

HAMDEN

A reinspection of the public water supply of the village of Hamden. was made by Mr. W. J. Erickson, sanitary inspector in this Department, on May 10, 1921. Previous inspections were made of this supply in 1908, 1915 and 1919.

Hamden is an unincorporated village of about 350 inhabitants, located in the central part of Delaware county on the western branch of the Delaware river. The supply is owned and operated by Mr. Howard D. Youmans of Delhi. The public water supply is derived by impounding Launt Hollow brook in a reservoir located about a mile from the village. From this reservoir the water is delivered to the consumers.

The watershed of Launt Hollow brook above the reservoir is about 4 square miles in area. The higher sections are rather steep and wooded. The lower sections along the stream are almost entirely devoted to farming and dairying purposes. There are about 50 inhabitants on the watershed at present. The conditions are as described in the previous reports. The houses, barns and out-buildings are located mostly very near or at the edge of the main or tributary streams. Cattle are pastured at several points along the stream.

In a report on an inspection of the supply dated June 10, 1921, the following recommendations were made:

1. That immediate steps be taken to remove all existing sources of pollution on the watershed of Launt Hollow brook tributary to the reservoir and to guard against their recurrence in the future.
2. That should any difficulty be experienced in removing the sources of pollution, the owner apply to this Department for the enactment of rules and regulations for the sanitary protection of the water supply.
3. That on account of the numerous sources of contamination and the impracticability of removing all these sources of contamination, the owner of the supply consider the abandonment of the present supply and the development of a safe and adequate supply.
4. That an expert on water supply development be employed to advise as to the best method of developing such a supply.

HARTWICK

A reinspection of the public water supply of the village of Hartwick, Otsego county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department on March 1, 1921. A previous inspection of the supply was made by this Division in the year 1913 and the report thereon published in the Annual Report of the Department for that year.

Hartwick is located about 18 miles north of Oneonta. The population is 550 about 80 per cent of whom receive the public water supply. The waterworks are owned and operated by the Hartwick Water Works Company of which Mr. J. M. Bush is president.

The water supply is derived from Barney Gulf brook about ½ mile east of the village, from a spring and from Cook pond. A deep well, located near the spring is used in case of emergency. The water flows by gravity to a distributing reservoir and thence to the village.

The Barney Gulf brook has a drainage area above the intake of about ⅛ of a square mile and is uninhabited. Cook pond above the intake has a watershed of about the same area on which is located one farm, the sanitary condition of which was apparently satisfactory. A ditch has been constructed near one side of the pond to divert the drainage of the hill nearby to a point in the brook below the intake. Ice is cut from the pond during the winter. The top of the basin of the spring is flush with the surface of the ground and it is possible that surface water may enter it. The deep well used as an auxiliary supply is located on a hill side remote from any habitation and should furnish a water of satisfactory sanitary quality.

No action has been taken by the village authorities on our previous recommendations in regard to the construction of a sedimentation basin, in regard to fencing the pond and distributing reservoir and in regard to requesting the enactment of rules and regulations for the protection of the supply.

In a report dated March 18, 1921, the following recommendations were made:

1. That the present careful supervision of the watershed be maintained.
2. That the wall of the Willis spring be raised a foot above the surface of the ground to prevent the entrance of surface wash and that the area around Cook pond be fenced off to prevent trespassing.
3. That the water company construct an impounding reservoir in Barney Gulf brook at a point near the present basin to provide storage and an opportunity for sedimentation.
4. That a competent engineer be retained by the water company to advise them as to the construction of the impounding reservoir and as to the most practicable method of removing the color.

HERKIMER

An investigation of the public water supply of the village of Herkimer was made by Mr. Earl Devendorf, assistant engineer in this Department, on November 24, and December 1, 1920. Previous investigations of the public water supply were made in 1917 and 1919 and reports thereon may be found in the Annual Report of the State Department of Health for the respective years. An additional investigation of the supply in connection with the typhoid fever outbreak was made in 1918 and a report thereon may be found in the Annual Report of the State Department of Health for 1919.

Herkimer is a village of 10,862 inhabitants according to the recent census and is located in the southern part of Herkimer county on the Mohawk river. A system of public sewers is provided throughout the village which discharges the sewage without treatment into the Mohawk river.

The water supply is owned by the village and operated under a municipal commission of which Mr. Arthur T. Clark is superintendent. The supply is derived by pumping from a series of driven wells known as the Harter Street wells, which are located in a sparsely settled portion of the village, and also from infiltration galleries, located northeast of the village near the West Canada creek. The water is pumped into the village distribution system, the excess over consumption going to a steel standpipe located on a hill north of the village. Practically all of the inhabitants are furnished with the public water supply. The total amount of water pumped as estimated from the pump strokes varies from 800,000 to 1,000,000 gallons per 24 hours.

As originally developed in 1918, there were 2 pumping stations at Harter street, which were connected to 12 driven wells located within an area 800 feet in length and some 100 feet in breadth. During the past year, however, one of these pumping stations has been removed and at present there are 11 wells connected to a steel vacuum tank 4½ feet in diameter and 12 feet in length having a capacity of approximately 14,500 gallons. The suction of the 8 x 10 triplex Gould pump is connected to this tank and discharges into the public distribution system.

The main pumping station which is located near the infiltration galleries along the West Canada creek also houses the municipal electric lighting plant. At the time of the inspection the construction of a new boiler house to accommodate two 400 horsepower Babcock & Wilcox boilers was partially completed. A new pumping station has been added adjacent to and north of the old pumping station and at the time of the inspection two 6-inch Manistee iron works centrifugal pumps, operated by 40 horsepower G. E. motors, to which they were directly connected, were in operation. These pumps are connected to a new infiltration gallery which has been constructed during the past summer some 500 feet north of the pumping station. This infiltration gallery is approximately 100 x 5 x 7 feet in dimensions. A wooden crib made up of hemlock lumber was first constructed in the bottom of the excavation which was approximately 23 feet below the surface. The wooden crib was first surrounded with large stone and then the excavation was covered with soil to the ground elevation.

In addition to the two centrifugal pumps, 2 steam pumps are to be located in the new pumping station and are to be connected to the old infiltration gallery. It is also planned to cross-connect these steam pumps with the piping from the new infiltration gallery in order to make available the 2 sources of supply for pumping either by electricity or by steam. The 1 pump, located on Harter street, was being operated at the time of the inspection only 16 hours per day and it is expected that when the changes contemplated at the main pumping station are completed, it will be unnecessary to use water from the Harter street wells. This pump will then be held for emergency use only.

During the past year the village authorities in charge of the public water supply engaged the Pitometer company of New York City to make a survey of the village distribution system for the purpose of determining first, the amount of slippage of the various pumps, second, the measurement of the total consumption and third the subdivision of the system into small sections in order to localize leakage and investigate the high rates of consumption.

The minimum rate of consumption was found to be 500,000 gallons occurring between 2 a. m. and 3 a. m. This rate includes the consumption of the New York Central and Hudson River Railroad, amounting to 90,000 gallons per day giving a rate, exclusive of industrial consumption, of 410,000 gallons per 24 hours. The leakage was found to amount to 361,000 gallons per 24 hours and consisted largely of service leaks. The present daily consumption is, therefore, as based on the record obtained on September 21 and 22, 1920, 600,000 gallons, exclusive of the industrial consumption or 57½ gallons per capita. The industrial consumption amounts to 212,000 gallons per 24 hours, giving a total consumption, as determined on the day of the test; of 812,000 gallons per 24 hours. The Pitometer company estimated that the village could save approximately 250,000 gallons per day by repairing the service leaks throughout the village.

At the time of the inspection complaints were received regarding the peculiar taste occurring in the village water. As a result of the investigation made on November 24 it was found that the new well had been in service some 2 weeks previous to the time of the inspection. A crib, made up of about 10,000 feet of hemlock lumber, was used in the construction of the well. The peculiar taste became less about November 24 and disappeared previous to the second inspection on December 1. It is alleged that the cause of the tastes noted was due to the new hemlock lumber used in the construction of this crib. At any rate information has been received from the authorities in charge of the water supply that no further trouble regarding tastes and odors have occurred in the public water supply.

At the time of the inspection chlorine was being applied at the Harter Street station at the rate of about 1½ pounds per 24 hours or, with the amount of water being pumped, at the rate of about .6 p.p.m. At the main pumping station chlorine was being used at the rate of about 7 or 8 pounds per 24 hours, giving an average rate of application of about 1.2 p.p.m.

At the time of the inspection it was learned that the new supply, which the village favorably voted upon in 1918 and which was to be obtained from Mill creek at a point near Gravesville, some 18 miles northwest of Herkimer, has not as yet been started although the money is available. This delay has been due to the desire on the part of the village authorities to await a reduction in the present high prices of both the material and construction costs.

At the time of the inspection it was learned that the intake with the conduit laid across the bed of the West Canada creek, which was formerly used as an auxiliary supply by pumping onto the surface of the ground surrounding the wells and by the utilization of 2 small sand filter units, the effluent from which was allowed to pass into the old infiltration well, has been discontinued since about the 1st of December, 1920. The direct connection, however, with the creek has not been used for some time. It is not expected with the new infiltration gallery in service that it will be again necessary to use sand filters in connection with the West Canada Creek water.

In a report dated January 14, 1921, upon an inspection of the supply the following recommendations were made.

1. That the authorities in charge of the public water supply continue the careful operation of the chlorination plant in order that a water of satisfactory sanitary quality may at all times be furnished the residents of the village.
2. That the use of the Harter Street wells, which, as pointed out in a previous report, are not very satisfactorily located, be discontinued unless a shortage of water should occur in the main source of supply, and for this purpose the pumping apparatus and chlorination plant should be held in readiness.
3. That the proposed plan of cross-connecting the steam and electric pumps so as to be able to pump with either electricity or steam power from either the old or new infiltration galleries be carried out at the earliest possible moment.

4. That the authorities in charge of the public water supply eliminate at the earliest moment the leakage which, as shown by the recent pitometer survey, mostly consists of service leaks.

5. That in case additional sources of water supply are necessary the village authorities follow the previous recommendations of this Department with respect to the construction of a 1 or 2 million gallon reservoir on the hill back of the village, this reservoir to store chlorinated creek water for fire purposes or other emergency and to supply any deficiency or consumption over that furnished by the present ground water supply, the ground water supply being pumped directly to the distribution system by ordinary use.

HICKSVILLE

A reinspection of the public water supply of the unincorporated village of Hicksville, Nassau county, N. Y., with special reference to an abandoned well now being used as a cesspool, about 500 feet northeast of the water plant was made by Mr. Henry Ryon, assistant engineer in this Department, on June 4, 1921.

Previous inspections of the supply were made by this Department in 1915, 1918 and 1920, and the reports thereon may be found in the Annual Reports of the Department for those years.

Hicksville is located about 27 miles east of New York City. The present population of the village is estimated at about 5,000, of which about 50 per cent are served with water from the public supply. The waterworks are owned and operated by the Nassau County Water Company, of which Mr. W. J. Drummond is president.

The water supply is derived from 2 drilled wells located under the pumping station and is delivered by pumping into 6 steel pressure tanks, from which it flows into the distributing system. The daily water consumption is estimated at about 190,000 gallons per day or 76 gallons per capita per day. The water is not treated. The two 8-inch wells are drilled in the bottom of a 9-foot brick-walled, cylindrical pit about 55 feet deep, located in the basement of the pumping station, the floor of which is some 8 feet below the surface of the ground, and extend to a total depth of about 115 feet below the surface. The pit was dry at the time of the inspection. The tops of both wells are sealed.

The pump room and the grounds around the plant were in fair sanitary condition. A dry closet is provided for the attendant's family which lives in the upper story of the pumping station. It is said that the contents of the containers of this closet are burned under the boiler. The sink wastes are discharged into a small leaching cesspool just outside of the building. There is a privy on the property about 100 feet east of the building, but it is apparently not in use. There are 8 or 10 houses within 300 feet of the wells, several of which were apparently new, indicating that the district is being rapidly improved. There is no sewerage system in the village and these houses all use privies or cesspools.

About 500 feet northeast of the plant is an old brick-walled well, said to be 10 feet in diameter and 80 feet deep, which was formerly used in connection with a brewery, but which is now being used as a cesspool. Although it formerly yielded a considerable amount of water it is now dry, a condition which is attributed by the inhabitants to the pumping of the well at the water works. The elevation of the ground water near the water plant is not definitely known, but its greatest depth, even during pumping, can be estimated from the fact that the cylinder on the pump is located about 60 feet below the surface of the ground, which would indicate that it probably cannot draw water from a depth of over 80 feet. Since the level at the well would probably be considerably lower than that 500 feet away it is difficult to see how the well would drain the cesspool unless its depth is somewhat less than 80 feet at which it is estimated. The fact, however, that the wells at the water plant and the abandoned well now being used as a cesspool are both probably in the same strata of water-bearing sand and gravel and only about 500 feet apart, makes it seem desirable that the well now being used as a cesspool should be cleaned and filled with earth in order to preclude the possibility of any pollution from it reaching the well of the public water supply.

The results of the analyses of the water taken at different times during the past few years indicate very high nitrates and very high and increasing quantities of chlorine, which show that polluting matter is reaching the well, and although there are numerous sources in the vicinity from which this pollution may come, it seems probable that this well or cesspool is one of them.

Numerous complaints have recently been received regarding tastes and odors in the water and also regarding an oily film on the water and a dark-brown sediment. From the description given these troubles appear to be due to iron in the water and possibly to growths of crenothrix. The analyses of the water bear out this conclusion. The iron is apparently to a large extent taken up from the pipes. Periodic flushing would undoubtedly improve conditions materially, although it is possible that an iron removal may be required to relieve the condition entirely.

In a report upon a reinspection of the supply, dated June 15, 1921, the following recommendations were made:

1. That the authorities in charge of the water supply develop a new source of supply, located at a considerable distance from the built-up portion of the village and free from all possible pollution.
2. That, pending the development of such a supply, all the privies and cesspools in the immediate vicinity of the plant be made watertight so as to prevent contamination of the supply, or a sewer system for the village constructed and all privies and cesspools abandoned and, if necessary, the water treated by the continuous application of liquid chlorine.
3. That the quality of the water be carefully watched and should evidence of active contamination be found the water be immediately sterilized by the continuous application of a suitable amount of liquid chlorine.

HOMER

An inspection of the public water supply of the village of Homer, Cortland county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 10, 1920. Previous inspections of the supply were made by this Division in 1912 and 1915 and the reports thereon published in the Annual Reports of the Department for those years.

Homer is located about 2 miles north of Cortland and has a population of 2800, of whom 70 per cent are served by the public water supply. The village has no sewerage system, the houses being served by cesspools. The waterworks are owned and operated by the village under a board of water commissioners, of which Mr. O. B. Andrews is president.

The water supply is derived from 4 driven wells located in the northwestern part of the village, and is pumped directly into the distribution system.

The wells are constructed of concrete and are covered with earth or planks. Within 500 feet of the wells there are 6 houses which have been provided with privies having concrete vaults and concrete cesspools for the disposal of kitchen wastes. Some of the privy vaults in the vicinity of the wells were ready to overflow and needed cleaning.

The previous recommendations of this Department, in regard to maintaining a careful oversight over the supply and in regard to filling the abandoned well with clean gravel or other suitable material and the discontinuance of dumping rubbish in the vicinity have been carried out. In a report dated January 25, 1921, the following recommendations were made:

1. That the authorities continue their careful supervision of the waterworks system.

2. That the contents of the privy vaults within 500 feet of the wells be removed at more frequent intervals and never allowed to reach a height of more than 6 inches below the top of the vaults.

HONEOYE FALLS

A reinspection of the public water supply of the village of Honeoye Falls, Monroe county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on March 21, 1921. A previous inspection of this supply was made in 1915 and the report thereon published in the Annual Report of the Department for that year.

Honeoye Falls is located about 15 miles south of Rochester and has a population of 1300, about 65 per cent of which is served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees, of which Mr. James Heath is president. The water supply is derived from two driven wells and a collecting well from which water is pumped into the distribution system.

The wells are located in a well-developed section of the village. There are from 8 to 10 privies visible within 100 to 300 feet or more from the wells.

The previous recommendations of this Department in regard to acquiring land around the wells, eliminating all sources of pollution, making cesspools watertight and providing privies with watertight containers, and making analyses of the water to detect the presence of active contamination, have not been carried out. An apparatus for the sterilization of the supply, with liquid chlorine, however, was installed in 1917.

In a report, dated April 21, 1921, the following recommendations were made:

1. That the municipal authorities in charge of the water supply immediately take steps to secure a new supply from a source satisfactorily located and free from possibility of pollution.

2. That, pending the installation of such a supply:

   (a) The authorities eliminate, as far as possible, all sources of pollution by providing watertight containers for all the privies near the wells, making all the cesspools in the vicinity watertight, removing the contents of the containers and cesspools to a remote place and disposing of them in a satisfactory manner when necessary, and maintaining such privies, cesspools and the surrounding area in sanitary condition.

   (b) The supply be sterilized by the continuous application of liquid chlorine at a rate determined by daily tests of the treated water by the plant operator for excess chlorine, in accordance with the instructions issued by this Department, but never less than 0.25 p. p. m.

In the connection with an outbreak of typhoid fever at Honeoye Falls a reinspection of the water supply was made on May 24, 1921. While it was found that the plant was not operating entirely satisfactorily, there was nothing to indicate that the water supply was connected with the typhoid outbreak. It was found, however, that the chlorination apparatus was operating satisfactorily and chlorine was being applied at the rate of a little less than 0.3 parts per million.

HOOSICK FALLS

A reinspection of the public water supply of the village of Hoosick Falls was made on August 22, 1921, by Mr. A. I. Howd of this Department, previous inspections of this supply having been made in 1912 and 1918. The village of Hoosick Falls is located in the northeastern part of Rensselaer county, about 40 miles north of Albany. The population of the village is 4,896 according to the census of 1920, about 80 per cent of whom are served with water from the public supply. The waterworks are owned and operated by the village under the direction of a board of trustees of which Mr. Salem H. White is president.

The water supply is derived from four dug wells located on low land near the Hoosick river, about ½ mile south of the village. All of the wells are connected but only one is provided with a suction pipe through which water is drawn to the pumping station, where it is chlorinated before being delivered to the consumers. The water is pumped directly into the mains, the surplus over consumption going to a storage reservoir from which the supply is drawn when the pumps are not operating. The water consumption is estimated at about one million gallons per day or some 250 gallons per capita per day. From the recent inspection it appears that some of the recommendations of the previous report have been carried out. The brick walls of the wells have been raised about 3 feet and the sides covered with concrete. The roofs of the wells have been repaired and are in general in a satisfactory condition. The regular water supply has been ample and it has not been necessary to pump from the river. A chlorination apparatus has been installed but at the time of the inspection had been out of use for several weeks, due to the fact that one of the connections had corroded. No scales are provided for weighing the chlorine cylinder in order to check the operation of the manometer on the chlorination apparatus. No records are kept of the amount of water pumped and of the amount of chlorine applied to the water. No tests are made for excess chlorine in the water in order to determine if the chlorine is being applied in proper quantities. No action has been taken on our previous recommendations that the village acquire land around the wells and surround them with dikes nor that in regard to diverting the flow of the brook carrying polluted water from the slaughter house, nor that the land around the well be fenced.

In a report on an inspection of the supply dated November 19, 1921, the following recommendations were made:

1. That the village authorities in charge of the public water supply carry out at once such of our previous recommendations as have not yet been acted upon, namely: that the village acquire land around the wells and surround them with dikes; that the flow of the brook carrying polluted water from the slaughter house be diverted from the wells and that the land around the wells be fenced.
2. That the chlorination apparatus be repaired and put into operation as soon as possible and continuously operated in an effective manner in order that a water of safe sanitary quality may at all times be furnished to the residents of the village.
3. That duplicate parts of the chlorination apparatus be obtained and kept on hand at all times in order to preclude any interruption in the sterilization of the public water supply.

HORNELL

A reinspection of the public water supply of the city of Hornell, Steuben county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on April 20, 1921. Previous inspections of this supply were made by this Division in the years 1908, 1909, 1913, 1916, 1917, 1918 and 1919, and reports thereon published in the respective Annual Reports of the Department for those years.

Hornell has a population estimated at 15,400, practically all of whom are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of public works, of which Mr. Fred A. Robbins is president.

The water supply is derived from three impounding reservoirs located on Carrington, Eveland and Seeley creeks, 5½ miles north of the city. The water is treated in a filtration plant consisting of six New York Continental horizontal filters of the pressure mechanical type. Alum is used as a coagulant. The filtered water is sterilized with liquid chlorine by means of two solution feed automatically controlled Wallace and Tiernan chlorinators.

The previous recommendations of this Department in regard to careful operation of the purification plant, the maintenance of sanitary conditions on the watershed and the control of algae growths by the use of copper sulphate have been carried out. No action has been taken, however, on the recommendation in reference to the construction of a coagulation and sedimentation basin for the treatment of the raw water.

In a report dated June 18, 1921, the following recommendations were made:

1. That the city authorities give careful attention to the operation of the purification plant in order to obtain as high a degree of efficiency as possible and construct a suitable coagulation and sedimentation basin for the treatment of the raw water before it enters the filters.
2. That the rate of application of the chlorine be determined by the use of the starch iodide test for excess chlorine.

INLET

An investigation of the water supply of the New Arrow Head hotel and an outbreak of diarrhea at Inlet, Hamilton county, N. Y., was made on September 2 and 3, 1921, by Mr. A. I. Howd of this Division.

Inlet is located in the town of Inlet, in the northwestern part of Hamilton county. It is at the southeast end of Fourth lake of the Fulton Chain of lakes, and is an attractive summer resort. A number of hotels and cottages are located at Inlet. According to the census of 1920, the population is 160, but during the summer season, the population is very much larger.

The investigation was made as a result of a communication from the proprietor of the New Arrow Head hotel in which it was stated that there was a slight epidemic of diarrhea at Inlet. The New Arrow Head hotel has a capacity of 100 guests, the population at the time of investigation being about 75. The outbreak, which was centered principally around the New Arrow Head hotel, begun about August 7, continued for about three weeks, and subsided quite rapidly at the end of the third week. During this period it was estimated that there were about 100 cases at the New Arrow Head hotel. At the Parquet, a boarding house and hotel nearby having a capacity of about 30 guests, it was estimated that there had been about 10 cases. Other hotels in the vicinity also had a number of cases.

The drinking water supply of the New Arrow Head hotel is obtained from springs in the mountain about one mile south of the hotel. The water from this source is piped to a tap in the kitchen and to a tap in the hall on each floor of the hotel. The water supply furnished to the wash bowls and toilets in the rooms and used for general purposes at the hotel, is obtained from Inlet creek at a point near the hotel. The sewage from the hotel is discharged into a double compartment septic tank about 10 feet by 20 feet by 5 feet deep, located in the rear of the hotel. The effluent from the tank flows through a pipe line into Inlet creek a few hundred feet above the intake of the water supply.

The waters of the spring from which the drinking water supply is obtained, flow over the ground for a short distance into a small reservoir formed by the construction of a masonry dam about 15 feet wide and 3 feet high across a narrow ravine. The intake consists of a 2-inch pipe provided with a strainer and is located near the bottom of the reservoir. The water flows by gravity through a 2-inch galvanized pipe to the hotel. The spring and reservoir are located in the woods far from any habitation, and apparently free from any permanent sources of pollution. The springs and reservoir are not fenced in to prevent the access of animals and people and the supply may, therefore, receive chance or wilful pollution. The amount of water that comes from this source is relatively small. At the time of the inspection there was only a small amount of water in the reservoir, the water being drawn down to the elevation of the intake pipe.

Inlet creek connects Fifth and Fourth lakes. From a point in the creek west of the Arrow Head, water is pumped into the mains at the hotel. This water is used for general domestic purposes at the hotel. It is the only water available in the guest rooms of the hotel and water is also available from taps in the kitchen. There are a number of different taps in the kitchen and apparently no marks or methods to distinguish which taps should or should not be used for drinking purposes. It was found at the time of the inspection that the help in the kitchen were ignorant as to the sources of water from the different taps.

The waters of Inlet creek are subject to considerable direct sewage pollution above the intake of the Arrow Head water supply. The nearest source of pollution is the discharge of sewage from the hotel itself. The effluent from the septic tank as pointed out above discharges into Inlet creek a few hundred feet above the water supply intake, and a few hundred feet above the Arrow Head, the effluent from the septic tank serving the Parquet hotel, discharges into Inlet creek. It is evident therefore that the water supply obtained from this source is considerably polluted and should not be used for any purposes, except possibly, flushing toilets, washing floors and other similar purposes. The water obtained from the creek should not be used for cooking purposes, for washing dishes or for any other purpose in the kitchen except washing floors. Signs are provided over the wash bowls in some of the rooms warning the guests not to use the water from the taps in the rooms for drinking purposes. One of the guests was interviewed who was taken sick shortly after his arrival at the hotel. He stated that the day that he arrived at the hotel he drank water from a tap in his room. The water is apparently used by guests for brushing teeth and washing and is therefore a source of danger and menace to health.

Another water supply, known as the Kenwell supply, is obtained from a small brook about 2 miles south of Inlet. This supply furnishes water to the New Arrow Head, the Parquet and other hotels and cottages at Inlet. The brook flows through swampy wood-land, apparently free from any permanent source of pollution, but subject to contamination from trespassers and animals on the watershed. The water from this source is highly colored and at times of heavy rains is very turbid.

The water supply for "The Wood" is privately owned and obtained from springs in the mountain. The owner of "The Wood" denied that there had been any cases of diarrhea or bowel trouble at his hotel.

In a report upon the inspection dated September 27, 1921, it was pointed out that the water supplies used by hotels and camps at Inlet are generally obtained from unsatisfactory and polluted sources or from sources unprotected from accidental or wilful pollution from trespassers and animals. The waters are generally high in color probably due to the vegetable matter with which the waters come in contact and are generally turbid after rains due to the fine wood-dirt in the beds of the shallow streams.

Due to the fact that, with a few exceptions, all the cases had left Inlet, it was difficult to trace and find the real cause of the outbreak. The possibility of the epidemic being due to such factors as milk, ice cream, vegetables and shellfish was considered and each factor practically eliminated. The general unsatisfactory condition of some water supplies and the highly polluted condition of others seems to be the real cause of the outbreak.

It was, therefore, recommended:

1. That the water supply derived from Inlet Creek and pumped into the mains at the New Arrow Head Hotel at Inlet, N. Y., be abandoned or the water so obtained be subject to filtration and sterilization before use.
2. That the water supply derived from the spring and reservoir in the mountain and used in the New Arrow Head Hotel for drinking purposes, be protected from accidental or wilful contamination by surrounding the reservoir and spring by a man and animal proof fence.
3. That the reservoir be cleaned of all vegetable matter as often as is necessary.

4. That steps be taken to improve the sanitary and physical quality of the Kenwell supply by protecting the stream and intake from trespassers and animals and by cleaning the stream of vegetable matter.

5. That the direct discharge of sewage from hotels, cottages and other places at Inlet into Inlet Creek be prohibited.

6. That the owners of the New Arrow Head Hotel, The Parquet, and any other hotels and cottages discharging sewage directly into Inlet Creek, be required to provide proper disposal works for the treatment of sewage from their properties, plans for which should be submitted to the state engineer and surveyor for approval, and permit for discharge of sewage from such works should be obtained from this Department in accordance with the provisions of chapter 510 of the Laws of 1921.

IRVINGTON

A reinspection of the sanitary condition of the public water supply of the village of Irvington was made by Mr. W. J. Erickson, sanitary inspector in this Department, on December 9, 1920. A previous inspection was made in 1916 and the report thereon may be found published on page 418 of the 37th Annual Report of this Department.

Irvington is an incorporated village of about 2,700 inhabitants located in the southern part of Westchester county on the west shore of the Hudson river about 23 miles north of New York City. The village is served by a public sewer system which has 3 outlets into the Hudson river into which the sewage is discharged unpurified. The public water supply, which is owned by the village under the direction of a board of water commissioners, is derived from a small stream impounded in a storage reservoir located about a mile east of the village. From this reservoir the water flows by gravity to the lower section of the village, roughly, that section west of the old Croton aqueduct.

The water for the upper section is supplied from a second or distributing reservoir located on a hill a little to the south of the first reservoir. The water is pumped to this distributing reservoir and thence distributed by gravity.

The average daily consumption is 400,000 gallons. A 4-inch cross connection has been made with the main of the Consolidated Water Company of Suburban New York in order to provide an auxiliary supply for use in time of drought or in case of a breakdown in the system. The storage reservoir is formed by the construction of an earthen dam across a small stream. The area tributary to the reservoir is about 300 acres, all of which has been purchased by the village. It is uninhabited and signs have been posted to warn against trespassing.

In a report on an inspection of the supply dated January 17, 1921, the following recommendations were made:

1. That the village authorities maintain strict supervision over the watershed in order to detect and prevent or abate any act or source of contamination found to occur.

2. That should it be found difficult to control the watershed so as to prevent all contamination the village consider the installation of apparatus for the sterlization of the supply by liquid chlorine.

ITHACA

A reinspection of the public water supply of the city of Ithaca, Tompkins county, N. Y. was made by Mr. Alfred Mullikin, a representative of this Department, on May 31, 1921. A previous investigation of this supply was made by this Department in the year 1915, and a report thereon was published in the Annual Report of the Department for that year.

Ithaca is located on the Delaware, Lackawanna and Western, and the Lehigh Valley Railroad. The present population is estimated at 17,000. Of the total population some 95 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of the board of public works. The water supply is derived from Six Mile creek, the water of which is impounded in a large reservoir having a capacity of 350,000,000 gallons, located at Potters Falls about two miles southeast of the city. From this reservoir the water flows by gravity to a mechanical filter plant located about three-quarters of a mile southeast of the center of the city. After filtration the water is delivered in part by gravity and in part by pumping to the distribution system. There are three distributing reservoirs, one at Mitchell street and one located at West Hill, one clear water reservoir adjoining the filter plant. Due to the topography of the city the distribution system is divided into two zones, forming a high and low pressure system. Water from the Mitchell street and East Ithaca reservoirs is supplied to the high pressure system. The average daily water consumption is approximately 2,500,000 gallons of which some 500,000 gallons are used by the large consumers leaving a daily domestic consumption of some 2,000,000 gallons or 117 gallons per capita. Since the last previous inspection the following changes have been made: At the filter plant, Wallace and Tiernan chlorination apparatus has been installed, together with a rotary air compresser for supplying compressed air used in washing the filters. New equipment has been provided at the pumping station.

The watershed of Six Mile Creek above this reservoir is approximately 45.3 square miles. The greater part of the population is scattered along the numerous highways which traverse the area. Pollution may enter the supply from the two railroads which traverse the watershed. There are, also two villages — Brocton, having a population of 320 and Slaterville, having a population of 397 — located on the watershed. Rules and regulations for the protection from contamination of the watershed were enacted in the year 1903, and frequent inspections of the shed are made by the authorities to discover and eliminate any possible sources of pollution. From the impounding reservoir the water flows by gravity to the filter plant, where it is mixed with aluminum sulphate. The water then flows into two coagulating basins operated in parallel. From the coagulation basins the water flows to the six filters, which are of the gravity mechanical type. After passing through the filters the water is sterilized by the application of liquid chlorine before it enters the clear water reservoir. From the clear water reservoir part of it flows to the low level district of the city and the remainder flows to the Van Natta pumping station where it is pumped into the distributing reservoirs of the high level district. Aluminum sulphate is fed under normal conditions at the rate of about 0.5 grains per gallon. This amount is increased in accordance with the turbidity of the water.

At the time of the inspection, water was passing through four of the units at the rate of 154,000,000 gallons per acre per day. The filters are washed when the loss-of-head reaches about 9 feet. The average filter run is about 45 hours. At the time of the inspection chlorine was being applied at the rate of 0.191 parts per million.

Daily routine analyses of the water are made by the superintendent in a small complete laboratory at the filtration plant. The analyses consist of examinations for turbidity, alkalinity, gas production and bacterial counts on agar and gelatin plates in both the raw and filtered water. The city authorities have also engaged the services of a consulting chemist to supervise the operation of the purification plant.

In a report on an inspection of the supply dated August 15, 1921 the following conclusions were made:

1. That at the time of the inspection the purification plant was being operated in an efficient manner and was producing a water of satisfactory sanitary quality.

2. That the authorities in charge of the water supply have carried out the previous recommendations of this Department.

It was therefore recommended:

1. That the authorities in charge of the water supply of the city of Ithaca continue to maintain careful supervision over the conditions on the watershed from which the supply is derived and over the operation of the purification plant.
2. That as an aid in determining the proper amount of chlorine to be applied to the filtered water, daily tests for excess chlorine be made by means of the starch iodide test, in accordance with the instructions enclosed.

JAMESTOWN

A reinspection of the public water supply of the city of Jamestown was made by Mr. W. J. Erickson, sanitary inspector in this Department, on December 17, 1920. Previous inspections were made of the supply in 1912 and 1915, reports upon which are published in the Annual Reports of this Department for the respective years.

Jamestown, a city of about 38,000 inhabitants, is located in the southern part of Chautauqua county, about 2 miles from Chautauqua lake. The city is provided with a sewer system which empties into the Chadakoin river below Falconer. The water supply is owned by the city and operated by the board of water and light commissioners, of which Mr. Lyman P. Hapgood is superintendent. The supply is derived from 15 driven wells located about 2 miles northeast of the city in the valley of the Cassadaga creek near its junction with the Chadakoin river. From these wells the water is syphoned into a receiving well, from which it is pumped to a reservoir in the rear of the Buffalo street pumping station. Thence it is pumped to the distribution system and to the new reservoir on English hill. The consumption varies from 3 to 3.5 million gallons daily. Of this amount the railroads use about 13,000 gallons for drinking water. The Erie railroad uses creek water for industrial purposes, but it is said that no cross connection exists between this and the city supply.

The Cassadaga creek has a watershed area of 140 square miles. During floods the stream overflows its banks and covers the area in which the wells are located. There are three or four cross connections with local industrial supplies which are derived from Chadakoin river. These are said to be provided with double check valves.

To augment the present supply the city is at present constructing a new pumping station and wells 2 miles up the valley from the present Levant plant. There are to be 10 siphons and 10 air wells.

In a report on an inspection of the supply dated February 10, 1921, the following conclusions were made:

1. That the public water supply of Jamestown was of a reasonably satisfactory sanitary quality at the time of the inspection.
2. That the quality of the supply is endangered by the presence of cross connections with industrial supplies.

It was therefore recommended:

1. That the city authorities continue to maintain a careful oversight of the sanitary condition of their water supply, especially during the flooding of the meadows in which their wells are located.
2. That the city authorities investigate the industrial supplies in order to locate any cross connection with the city supply and to eliminate the same if practicable, and that if not practicable to eliminate these cross connections they be provided with double check valves in accordance with the general plan approved by this Department.

JOHNSTOWN

A reinspection of the public water supply of the city of Johnstown was made on January 4, 1921, by Mr. A. I. Howd, assistant engineer in this Department. Previous investigations of this supply have been made by the Department in 1914 and 1918.

The city of Johnstown, located in the southern part of Fulton county, has a population of about 11,300, approximately 95 per cent of which is served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners, for which Mr. L. Hillabrandt is superintendent. The water supply is derived from Cold brook, Warren brook and Cork Center brook, streams located a few miles west of the city.

Since the previous inspection a number of improvements have been made in the waterworks system. The dam of the old Cork Center reservoir has been raised, increasing the capacity of the reservoir from 700,000 to about 2,000,000 gallons. The new Cork Center storage reservoir, which was in process of construction at the time of the previous investigation, has been completed and put into use. This reservoir, which is formed by the construction of the dam across Cork Center brook about ½ mile above the old Cork Center reservoir, has an estimated capacity of 160,000,000 gallons. The dam was constructed by earth fill and has a concrete core wall.

The watersheds tributary to Warren and Cold Spring Brooks reservoirs are relatively small, are unpopulated and are not crossed by highways. There is little opportunity for contamination of the supply obtained from this source. The watershed above the intake of the Cork Center supply is uninhabited but is crossed, however, in different places by highways. It was noticed at one point where a highway crossed the brook entering the reservoir that a path had been made down to the stream by automobilists, undoubtedly to obtain water. This source of supply may, therefore, especially during the summer, be subject to accidental or wilful pollution from trespassers on the watershed.

In August, 1918, the city installed an apparatus for the sterilization of the supply by liquid chlorine. The apparatus is a manual control, direct feed type M D B chlorinator, manufactured by Wallace & Tiernan. Scales are provided under the chlorine cylinder for determining the amount of chlorine applied to the water. The manometer of the apparatus was not operating at the time of the inspection.

In a report dated February 7, 1921, the following recommendations were made:

1. That the authorities in charge of the water supply continue their careful and effective patrol of the watersheds of the streams from which the water supply of the city of Johnstown is obtained.
2. That the authorities in charge of the water supply continue to operate the chlorination apparatus with care and efficiency at all times.
3. That the manometer of the chlorinator be repaired and kept in operation.
4. That daily tests be made for excess chlorine, so that the proper amount of chlorine may be applied at all times.

The latter part of October, this Department was notified that, due to numerous complaints of tastes and odors from the water, the water commissioners of Johnstown had ordered the chlorination of the water supply discontinued. An investigation was immediately made by this Department on October 28, 1921, and a report dated November 14, 1921, was prepared, which pointed out the following facts:

1. That the physical condition of the water supply of the city of Johnstown was very unsatisfactory, due to the objectionable odor and tastes of the water supply caused by the presence of aquatic growths in the reservoirs.

2. That the tastes and odors in the city water were not due to the very small amount of chlorine applied, which in itself was probably insufficient to properly sterilize the supply.
3. That, while the authorities in charge of the water supply have in part carried out the previous recommendations of this Department in installing a chlorination apparatus, the operation of this apparatus was discontinued on October 25, 1921, by order of the board of water commissioners.
4. That the discontinuance of the sterilizing of the supply is a procedure which cannot be considered safe, and which may give rise to an outbreak of water-borne disease upon infection entering the supply from the numerous opportunities noted in the above report.
5. That opportunities for contamination of the new Cork Center supply exist, not alone due to the existence of two summer camps on the watershed and the highway crossings, but from the accidental, incidental or wilful pollution of hunters, fishermen or trespassers upon the watershed.

It was therefore recommended:

1. That the authorities in charge of the public water supply of Johnstown immediately resume sterilization of the water from the old Cork Center distributing reservoir, applying liquid chlorine at a rate to be determined in accordance with the results of daily tests for excess chlorine as outlined in the instructions issued by this Department, a copy of which is attached to this report.
2. That the authorities in charge of the public water supply take immediate steps to remedy the objectionable conditions existing in the reservoirs giving rise to the occurrence of the disagreeable tastes and odors in the public water supply, by removing the present growths mechanically and by treating with copper sulphate, in accordance with the procedure outlined in the body of this report, in order to prevent their recurrence.
3. That the authorities in charge of the public water supply continue their careful supervision of the supply, making frequent inspections of the watershed, in order to discover and eliminate any possible sources of pollution that may be found to exist.

KAATERSKILL

An inspection of the water supply of the Ulster and Delaware railroad, at Kaaterskill, N. Y., was made by Mr. W. J. Erickson, sanitary inspector in this Department, on June 10, 1921.

Kaaterskill station is located at the outlet of South lake, in the town of Hunter, in the southeastern part of Greene county. This section is a noted summer resort and many hotels and camps are located in the vicinity. Except for a saw mill there are no buildings in the vicinity of the station. The water supply, which is used only to fill the water tank on the coaches of the branch line of the railroad, is derived from a spring located about 1,000 feet east of the railroad and about 30 feet north of the track.

The spring water comes to the surface at the foot of North Mountain, in a circular well of flat stone slabs. The well is not protected from surface wash nor is it covered. The water is obtained by dipping a bucket into the well. The mountain side above the spring is uninhabited and is crossed by only one road which is about a half mile above the spring.

In a report on an inspection of the supply dated July 31, 1921 the following conclusions were made:

1. That the spring should yield a satisfactory water if properly protected from surface wash.
2. That the spring is not protected from surface wash and the method of drawing the water is unsatisfactory.

It was therefore recommended:

1. That the spring be protected from surface wash by extending th wells and covering it.

2. That a more satisfactory method other than dipping into the sprin be developed for obtaining the water.

KEESEVILLE

A reinspection of the public water supply of the village of Keesevill Essex county, N. Y., and of a number of proposed new sources of publi water supply was made by Mr. Alfred Mullikin of this Division on Novemb 3, 1921. Previous inspections of this supply have been made by th Division in 1915 and 1920 and the reports thereon published in the Annu Reports of the Department for those years.

Keeseville, a village with a present population estimated at 1,800 located in the northwestern part of Essex county, 5 miles west of La Champlain. Of the total population approximately 42 per cent are serv with water from the public water supply. The waterworks are owned an operated by the municipality under the direction of a board of water co missioners of which Mr. W. S. Greene is president. The water supply derived in part from the Ausable river and in part from a deep well, driv through rock in the south bank of the river near the center of the villag The water from the well is only used in case of emergency as the yield inadequate to meet the demands of the village and the supply is of unsatisfactory sanitary quality. From the Ausable river or the well, wat is delivered by pumping into the distributing system. The average dai water consumption based upon an average of 10 strokes per minute of t Lang pump amounts to approximately 468,000 gallons per day or over 6 gallons per capita.

Storage is provided by an equalizing rectangular reservoir located 1 miles southeast of the village at an elevation of some 280 feet. The reserv has not been used since 1917 as there has not been sufficient power fro the present pumps and waterwheels to pump the water to such an elevati The water from Ausable river flows by gravity through a wooden flume locat along the south bank of the river into the pumping plant. The locati of the pumping plant is about in the center of the village at the river ba The driven well, located under the pumping station, is only used during t months of July, August and September. The well is located in the cen of the thickly settled community. This well was driven to a depth of 50 feet but after repairs, was found to be 420 feet deep. When the pump in operation it draws water from all other wells in the locality and it claimed by the superintendent that it can be pumped dry in 48 hours.

The watershed of Ausable river above Keeseville is approximately 476 squ miles. There are a number of villages and hamlets located in the ri valley which consists of precipitous slopes of the Adirondack Mountai The principal villages and their populations consist of Clintonville, 2 Ausable Forks, 2,000; Jay, 200; Upper Jay, 525; Keene, 200; Keene Vall 400; Wilmington, 100; Lake Placid, 2,099 and Newman, 200; giving a to population of approximately 6,000. Some of the above named villages se directly into the river. The village of Lake Placid has settling tanks filter beds, the effluent from which finally reaches the river. At Aus Forks the sulphite wastes from the paper pulp mill enter the stream. F the recent inspection it appears that conditions remain practically described in the previous report and that our recommendations have been acted upon. Since it is generally known by the village authori that both sources of supply are polluted, the authorities have had u consideration the acquisition of a new source of water supply from any of the following sources: One proposed source of supply known as S springs located some ¾ of a mile southwest of the village on the north of the Ausable river, consists of an undeveloped area giving evidence of existence of some 6 or 8 springs which, at the time of the inspection, delivering a total amount of water of about 100 gallons per minute which is insufficient to supply the village. These springs are located on pasture land and are subject to considerable pollution. Another proposed source of supply consists of Bushea springs located some ¾ of a mile south of the village on the south side of Ausable river and consists of one small spring of good sanitary surroundings which, in itself, is insufficient to supply the village. A third source consists of a supply from Augur lake which is located about 3 miles south of the village. This lake also receives water from Butternut pond and has a drainage area including that of the pond of 13½ square miles. The watershed is sparsely populated but is subject to pollution from eight or ten houses and from pasture land. All of the three sources mentioned above would necessitate pumping the water into the village distributing system. A fourth proposed source is Butternut pond, located about 5 miles south of the village. This pond has a drainage area of 7½ square miles and is subject to pollution similar to that of Augur lake, with the exception that there are not over ½ dozen houses on the watershed. It has been the desire of the village officials to obtain a supply which shall be both adequate in quantity and of a satisfactory sanitary quality and which will not necessitate pumping.

In a report on an inspection of the supply dated November 21, 1921 the following conclusions were made:

1. That the present sources of public water supply as obtained from the Ausable river and the deep well are subject to serious and dangerous contamination and are of a very unsatisfactory sanitary quality and unsafe for human consumption.
2. That the present pumping machinery is inadequate or else serious leaks exist in the distributing system as it is impossible to pump water into the reservoir.
3. That the authorities in charge of the water supplies have not carried out the previous recommendations of this Department.
4. That the proposed source of water supply known as the Smith springs is probably inadequate in its present undeveloped state and was of an unsatisfactory sanitary quality at the time of the inspection.
5. That the proposed source of water supply known as the Bushea springs while of a fairly satisfactory sanitary quality, is in all probability too small to be considered as a satisfactory source of supply.
6. That the proposed source of water supply known as Augur lake while adequate in quantity is of questioned quality being subject to pollution, and would require some form of purification and pumping.
7. That the proposed source of water supply known as Butternut pond, while both adequate in quantity and so located as to probably eliminate the necessity of pumping, is at a considerable distance from the village and is of questionable quality being subject to some pollution which would necessitate sterilization with liquid chlorine.

It was therefore recommended:

1. That the village authorities in charge of the public water supply take immediate steps to carry out the previous recommendations of this Department concerning the acquisition of a public water supply that shall be both adequate in quantity and of a safe sanitary quality at all times.
2. That in view of the complicated hydraulic questions involved, the village authorities should retain the services of a competent sanitary engineer to advise them regarding the various available sources of supply and outline the best and most economical means of development.
3. That, as previously recommended, pending the installation of a new supply of satisfactory sanitary quality the village should immediately install a chlorination apparatus for the sterlization of their present supply with liquid chlorine.
4. That before any new source of supply is developed the village authorities should receive the approval of the State Water Power Commission in accordance with the provisions of Section 499 of the Laws of 1921.

LAKE GEORGE

A reinspection of the public water supply of the village of Lake George, was made by Mr. Earl Devendorf, a representative of this Division on June 1, 1921. Previous inspections have been made in the years of 1908 and 1919 and the reports thereon published in the Annual Report of the Department for the respective years.

Lake George is an incorporated village located in the southeastern part of Warren county at the southern end of Lake George. The village has a resident population estimated at 1,200 which is greatly increased during the summer months, as the village is a very popular summer resort. The entire population is supplied with the public water supply which is furnished by the Lake George Water Company of which Mr. E. J. Worden and Mr. S. M. Bates are owners. The water supply is derived from impounded reservoirs located on three small surface water streams west of the village. From the reservoirs the water is delivered by gravity through a distributing system.

In addition to the above regular source of water supply an auxiliary water supply is taken from Warrensburg brook which is used only in times of drought to supplement the supply from the other streams. At the time of the inspection it was stated that it had not been necessary to use the Warrensburg creek, the auxiliary source of supply. The watershed area tributary to the reservoirs used and the main source of supply amounts to some 5¾ square miles which is wholly timbered, and apparently free from any permanent source of pollution. From the recent inspection it appears that the waterworks officials have endeavored to maintain the regular supply in a satisfactory, sanitary quality; that the use of Warrensburg creek has not been necessary, and for that reason the sterilization plant has not been installed.

In a report on an inspection of the supply dated October 5, 1921, the following conclusions were made:

> 1. That while the regular public water supply of the village of Lake George is derived from sources which are apparently free from opportunities for pollution and should prove satisfactory from a sanitary quality although at times affected to some extent by surface run-offs at times of rainfall, the emergency supply derived from Warrensburg brook is subject to pollution from the population existing on the watershed and from the surface wash of the state highway and as previously pointed out, cannot be considered as a source of public water supply without adequate purification.
>
> 2. That the water Company has endeavored to maintain careful supervision over the main source of supply and have not resorted to the use of Warrensburg brook. It was therefore recommended that the Water Company continue careful supervision of the regular supply in order to prevent any contamination and that the emergency supply derived from Warrensburg brook be not used unless it is first sterilized by means of liquid chlorine or hypochlorite of lime as pointed out in the previous report.

LAKE PLACID

A reinspection of the public water supply of the village of Lake Placid, was made by Mr. Earl Devendorf, a representative of this Division on July 29, 1921. Previous investigations of this supply have been made by this Division in 1911, 1914 and 1919 and reports thereon printed in the Annual Reports of the State Department of Health for the years 1911, 1914 and 1920 respectively.

Lake Placid is an incorporated village in Essex county located on the shores of Mirror lake, a small lake emptying into the west branch of the Ausable river. The resident population is about 1,800, while the summer visitors increase it to about 6,000, all of which are served with the public water supply. The public water supply is owned by the village and operated under a board of trustees. The water supply is derived by pumping from Lake Placid. The chlorination plant for the treatment of the supply was installed in 1918. Besides serving all of the village, the supply is served to the camps of the Whiteface Inn district, Buck island and Ruisseaumont district. Lake Placid has a water surface of some 3.2 square miles and a total drainage area of 20.7 square miles. There are some 75 summer cottages and camps along the shore of the lake. The Shore Owners Association have cooperated with the village authorities to prevent the pollution of the supply by providing disposal systems and in some cases by pumping sewage a considerable distance from the lake. However, as the lake is used considerably for bathing, boating and fishing during the summer months there are possibilities of pollution from these sources. The recent inspection was made as a result of the desire of the village authorities to improve the sanitary conditions existing on the watershed tributary to the lake and at the request of the authorities this Department has prepared and submitted tentative rules and regulations for the sanitary protection of the public water supply of Lake Placid in accordance with the provisions of the Public Health Law. As soon as these rules have been approved and returned by the village authorities they will be enacted by the Department. At the time of the inspection it was found that the conditions surrounding the supply were approximately the same as described in the previous reports. The chlorination plant however, was not in operation and it had not been operated for some time, on account of complaints from the consumers regarding the objectionable tastes and odors alleged to occur in the water and attributed to the application of chlorine. The need for the continuous application of chlorine to the supply during the summer months was again pointed out to the village officials and the apparatus was placed in operation. The attendant was instructed in its use and how to make tests for excess chlorine in the treated water in accordance with the so-called starch iodide test.

In a report on an inspection of the supply dated December 31, 1921 the following conclusions were made:

1. That while the public water supply of Lake Placid is comparatively free from the possibility of contamination during the winter, it is subject to opportunities for contamination during the summer months from the large summer population.

2. That the village authorities have received for their approval a copy of the rules and regulations prepared by this Department for the sanitary protection of the public water supply of Lake Placid.

3. That the chlorination plant was not in operation at the time of the recent inspection.

It was therefore recommended:

1. That the village authorities continue their careful supervision and sanitary patrol of the watershed in order to discover and eliminate any sources of pollution and as a means of assisting in this supervision the authorities should return with their approval the rules and regulations prepared by this Department for the sanitary protection of the public water supply of Lake Placid.

2. That the authorities in charge of the public water supply maintain careful supervision of the operation of the chlorination apparatus in order that a water of safe sanitary quality may be assured the residents at all times.

LARCHMONT

A reinspection of the public water supply of the village of Larchmont was made by Mr. Earl Devendorf, a representative of this Division, on July 18, 1921. Previous investigations of the supply have been made by this Department in 1911, 1912, 1915, 1916 and 1917 and the reports thereon published in the Annual Reports of the Department for those years.

Larchmont is an incorporated village located in the southeastern portion of Westchester county, about 19 miles from New York city. The resident population amounts to some 2,400 inhabitants. During the summer time, however, the population is said to be increased by the influx of summer visitors to some 6,000 or 7,000. Practically the entire population is served by the public water supply. The waterworks are owned and operated by the Larchmont Water Company of which Mr. William Murray is president and superintendent. The water supply is derived from the Sheldrake river at a point about 2½ miles northwest of the village. The water is impounded by three storage reservoirs, from the lower one of which the water flows by gravity through pressure mechanical filters. The effluent from the filters is sterilized by means of liquid chlorine before it is delivered to the village. The average daily consumption varies from a minimum of 225,000 gallons per day during the winter to a maximum of some 400,000 gallons per day during the summer. Since the last previous inspection a new Wallace and Tiernan automatic control chlorination apparatus has been installed to replace the old electric-bleach apparatus which had become disintegrated. The chlorine is applied to the effluent from the filters by means of a Ross water injector pump.

The watershed tributary to the supply is approximately 2½ square miles in area. While the watershed is not densely populated there are numerous opportunities for contamination of the supply from residences on the watershed in the vicinity of the river. This area is however being rapidly built-up, especially in certain districts and unless adequate precautions are taken to prevent the improper location of cesspools and sewers the supply will be grossly contaminated from these sources. At the time of the inspection a Boy Scouts' camp was observed at the upper end of Carpenters pond. At this camp a latrine was maintained within 25 feet of the river. The land on which the camp was situated is owned by the water company and the camp authorities have been advised by the company that they could not continue to camp here in the future. At the time of the inspection no algae were observed in the reservöir but copper sulphate had been applied, during the past year. The superintendent stated that the organisms usually found in the reservoir were asteronella, synedra and other diatoms. He stated, however, that the use of copper sulphate had been successful in eliminating the growths and had been applied in accordance with the recommendations of the Pease Laboratories. Through the by-pass raw water can be delivered directly to the village at times when the filters are out of commission.

It was therefore recommended in a report dated August 30, 1921:

1. That the authorities in charge of the village water supply carry out at once such of our previous recommendations as have not as yet been acted upon and which are given in the body of this report.
2. That the authorities in charge of the public water supply provide a duplicate chlorination plant or sufficient duplicate parts of the chlorination apparatus to insure the constant and continuous sterilization of the public water supply.
3. That the present unsuitable filter media be replaced with suitable media preferably having an effective size ranging from 0.3 to 0.4 mm and a uniformity coefficient not greater than 3.0.
4. That the company consider a rearrangement of the present filters so as to apply alum in a constant uniform manner by means of a dry feed apparatus.
5. That the Company endeavor to operate the purification plant in such a manner as to produce a water of good sanitary quality at all times.

LAURENS

A reinspection of the public water supply of the village of Laurens, Otsego county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on February 28, 1921. A previous inspection of the supply was made by this Division in the year 1914 and a report thereon published on page 369 of the Annual Report of the Department for that year.

Laurens is located 8 miles north of the city of Oneonta. The present population is 365, of whom practically all are served by the public water supply. A few families outside of the incorporated village limits are also served from this supply. The waterworks are owned by the village and are under the control of the board of trustees, of which Mr. S. C. Millard is president. The water is derived from two groups of springs, one group located near a hill a mile southeast and the other on the hillside three-quarters of a mile southeast of the village. There is a distributing reservoir of masonry construction located half a mile southeast of the village. The water is distributed by gravity through the distributing system. The four springs near the hill and the three springs on the hillside have been developed by the construction of circular concrete basins. About 200 feet east of the reservoir on the hillside another spring has been developed by a shallow square excavation. The upper end of the basin is flush with the surface of the ground and easily permits the entrance of surface wash. At the time of the inspection the heavy snows were beginning to melt and it was observed that considerable surface water made its way into the basin through the natural shale rock which formed the walls of the basin.

In a report on an inspection of the supply dated March 17, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply provide concrete walls, extending these about a foot above the surface of the ground, for those springs that are not as yet protected from surface wash and also enclose with a suitable woven wire fence those springs that are not protected from chance or wilful contamination.
2. That drainage ditches be dug above all the springs to divert the surface wash.

LE ROY

An investigation of the sanitary quality of the public water supply of the village of Le Roy was made by Mr. Henry Ryon, assistant engineer in this Department, on January 5, 1921. A previous inspection of this supply was made on August 21, 1917, and a report thereon will be found on page 381, Volume II, of the 38th Annual Report of this Department.

Le Roy is an incorporated village of 4,700 inhabitants, located in the western part of Genesee county, about 25 miles southwest of Rochester. The water supply is owned by the village and operated by the board of water and light commissioners, for whom Mr. E. G. Middleton is superintendent. There is no comprehensive sewer system in the village. There are, however, a few sewers and drains, most of which have been built by private parties, which serve the built-up portion of the municipality and discharge their sewage into Oatka creek, a small stream which flows through the village. The remainder of the village is served by leaching cesspools. The public water supply is derived from the upper part of Mud creek, the water being collected in an impounding reservoir of 175,000,000 gallons capacity, at a point about 6 miles south of the village, whence, after treatment in a rapid sand filter plant, located just below the dam forming the reservoir, it flows through a 16-inch main to the village distribution system, the surplus going to a standpipe and an elevated tank. The elevation of the top of the standpipe is several feet below the water level in the clear water basin at the filter plant, and for that reason some difficulty is being experienced, due to the standpipe overflowing. It is understood, however, that it is intended in the near future to raise the tank and thus avoid the trouble from this source. About 85 per cent of the population is served with water from the public supply. The consumption is estimated at about 210,000 gallons per day, or 65 gallons per capita per day, but, since there are no means of measuring the flow of water, this estimate is probably not very accurate.

The area of the watershed from which the supply is derived is approximately 1.7 square miles. The total population of this area is between 25 and 30 persons, or about 17 persons per square mile. In general, the watershed consists of gently sloping land, used principally for farming. The village owns considerable land in the immediate vicinity of the reservoir. The buildings on the watershed are in general located well back from the stream, and there appears to be little opportunity for direct contamination of the water.

The treatment plant, which, as stated above, is located immediately below the dam, consists of an aerator, a coagulation basin, two open gravity sand filters and a clear water basin. The water passes first from the reservoir to the aerator, which is housed in a small ell at the northwest corner of the building provided with louvers for ventilation. From the aerator heads it falls into a small shallow basin, from which it passes downward through a vertical Venturi tube into the coagulation basin, a concrete chamber of about 40,000 gallons capacity, an equivalent of approximately 4 hours' detention, located under the floor of the filter house. A float in this basin connects to a valve in the inlet to the aerator, and maintains a constant level in the basin by regulating the flow to the aerator. Alum is applied to the water as it passes through the Venturi from the aerating chamber to the coagulation basin by an automatic valve actuated by the Venturi. It was stated that from 50 to 60 pounds of alum are used per day.

In a report upon the supply dated January 31, 1921, the following conclusions were made:

> 1. That the water supply of the village of Le Roy was not in a satisfactory condition at the time of the inspection.
> 2. That the filter plant was not being operated in such a manner as to effectively purify the water.
> 3. That no means are provided at the filter plant for measuring the quantity of water and thus regulating the rate of application of the coagulant.

It was, therefore, recommended:

> 1. That the quantity of alum applied to the raw water be regulated in accordance with the condition of the raw water, and that sufficient alum be applied at all times to cause the formation of a suitable flock and obtain effective results from the process of filtration.
> 2. That means be provided for accurately measuring the quantity of water treated.
> 3. That a careful record be kept of the amount of water treated and the quantity of alum applied to the water.
> 4. That several hours be allowed to elapse between the washing of one bed and the washing of the other.
> 5. That the first filtrate after washing be wasted for at least 15 minutes by means of rewash valves provided for that purpose.
> 6. That if, after carrying out the above recommendations, it is found that the plant does not yield a water of unquestioned purity at all times, a chlorinating apparatus be installed and put in operation.

LILLY DALE

A reinspection of the public water supply of the unincorporated village of Lilly Dale, Chautauqua county, N. Y., was made by Mr. Alfred Mullikin of this Division on August 29, 1921. A previous inspection of this supply was made by this Division in 1915, and a report thereon published in the Annual Report of the Department for that year.

Lilly Dale is a religious settlement with a present population estimated at 200 in winter and 400 in the summer. It is located on the east shore of Cassadaga lake, about 9 miles south of the city of Dunkirk. Of the total population all are served with water from the public water supply. The waterworks are owned and operated by the Lilly Dale Assembly under the direction of a board of trustees. The water supply is derived from two sources, one being taken from Upper Cassadaga lake and the other from about five driven wells located in various sections of the village. From the lake the water is delivered by pumping into a distribution system. The average daily water consumption is approximately 21,000 gallons, or 50 gallons per capita. Storage is provided by 2 standpipes.

There are three lakes in the chain of lakes known as the Cassadaga lakes. The water enters Upper lake from the east and flows very slowly through a channel to Middle lake and thence to Lower lake. The watershed tributary to Upper lake, the source of water supply, has an area of about 4 square miles. With the exception of the thickly populated area on the east side of the lake, there are very few houses on the watershed. The houses on the east side, however, are provided with a sewer system, the sewage from which is treated in a settling tank and discharged into Middle lake. At the time of the inspection the water of Middle lake was very turbid, and appeared to be receiving considerable pollution from the sewage disposal plant. Upper lake is also subject to pollution by people using the lake for bathing and boating. It is claimed that the water is not used for drinking purposes on account of possible contamination of the supply from the sewage disposal plant, but is maintained for fire protection, washing and sprinkling purposes.

There are 5 public wells, used as a source of drinking water supply, located at the following places: Melrose park, Forest temple, The Village Cafeteria, The Maplewood hotel and Leolyln hotel. These are apparently driven wells and are located in thickly settled parts of the community. They are not adequately protected from surface wash, and there are sewers generally within a relatively short distance of them. Three of the wells are housed in small wooden sheds. Each well is provided with a hand pump. From the recent inspection it appears that the recommendations of this Department have been only partially carried out. A sewerage system has been installed and a settling tank provided for the treatment of the sewage. The water supply pumped from Upper lake, however, is not sterilized, the public wells have not been abandoned, nor has an application been made for rules and regulations for the protection of the watershed.

It was therefore recommended in a report dated October 11, 1921:

1. That the authorities in charge of the public water supplies immediately carry out the previous recommendations of this Department, namely, that a suitable apparatus be installed for the sterilizing of the Upper lake water supply with liquid chlorine; that application be made to this Department for the enactment of rules and regulations for the protection of the supply.
2. That the wells at the Maplewood Hotel and Forest Temple be abandoned immediately.
3. That the other wells be abandoned when the main water supply has been improved and rendered satisfactory from a sanitary standpoint.
4. That additional treatment of the sewage from the village sewer system be provided in order to lessen the possibility of contamination of Upper lake supply.

LIMA

A reinspection of the public water supply of the village of Lima, Livingston county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on March 22, 1921. A previous inspection of the supply was made by this Division in the year of 1916, and a report thereon published in the Annual Report of the Department for that year.

Lima is located 20 miles south of the city of Rochester. The present population is estimated at 1,000. Of the total population 90 per cent are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees, of which Mr. H. Allen Sylvester is president. The water supply is derived from a shallow well located 1¼ miles west of the village. From the well the water is delivered by pumping into a storage reservoir located on a hill about 600 feet west of the pumping station. From the reservoir the water flows through the village distributing system. The average daily water consumption is approximately 60,000 gallons, or 66 gallons per capita. Since the last previous inspection a new 24-horsepower gasoline engine and Rumsey triplex pump have been added to the plant.

The well is situated at the foot of the hill on which the reservoir is located. There were apparently no direct sources of pollution in the vicinity of the well at the time of the inspection. The barn near the well, which formerly constituted a possible source of pollution, is no longer in use. The nearest barn in use is at a distance of more than 500 feet from the plant. The village now controls an area of 10 acres in the vicinity of the pumping plant.

In a report on an inspection of the supply dated April 27, 1921, the following conclusions were made:

1. That the water supply at the time of the inspection was very hard but of a satisfactory sanitary quality.

It was therefore recommended:

1. That the authorities in charge of the water supply carry out our previous recommendation, that a fence be constructed enclosing the area near the well to prevent trespassing and to keep animals away from the well.
2. That the authorities continue to maintain a careful supervision at all times over the water supply.

LYONS

A reinspection of the public water supply of the village of Lyons, was made by Mr. W. J. Erickson, sanitary inspector, on April 11, 1921. Previous inspections were made in 1908, 1910, 1916 and 1919, the reports upon which are found published in the Annual Reports of the Department for the respective years.

Lyons, which is a village of about 5,000 inhabitants, is located in the southern part of Wayne county about 50 miles west of Syracuse. The village is provided with a comprehensive sewer system which empties into the Barge canal after passing through a disposal plant consisting of Imhoff tanks and sprinkling filters. About half of the population of the village is served by the public water supply, owned and operated by the village under the supervision of the municipal board of which Mr. H. F. Zimmerlin is superintendent. The supply is derived from five small lakes or ponds located about 8½ miles south of the village. From the intake which is located at the outlet of the lowest lake the water flows by gravity through a gravity mechanical filter. After sterilization with liquid chlorine the water is pumped from the clear water basin through the distribution system to a steel standpipe. A second standpipe is kept full for use in case of emergency. The average consumption in the village is about 200,000 gallons a day with a maximum of 350,000 gallons. In general the water system remains as described in the report on the inspection of 1916.

The area tributary to the ponds from which the supply is derived, is about ¾ of a square mile. The ponds are largely spring fed. There are but two houses on the watershed which are located at some distance from the ponds. However, the area is devoted to agriculture and is accessible to fishermen, bathers and other trespassers. Rules and regulations for the protection of the supply were enacted by this Department in 1916. Considerable trouble is experienced by the excessive growths of algæ, particularly in the lowest pond and shallow channel formed by the dam at the intake.

Several improvements have been made at the filtration plant since the previous inspection. The loss of head gauges have been repaired. Scales have been provided for checking the amount of chlorine used, curbing has been provided from the manholes to the clear water basin and the amounts of alum and liquid chlorine applied have been increased. The plant was not in operation at the time of the inspection though the operator cleaned one of the beds for demonstration of the procedure followed.

At the time of the 1919 inspection it was pointed out that while the public water supply of Lyons was of good quality from a sanitary standpoint it was seriously affected as to its æsthetic quality by the occurrence of algæ growths at certain seasons of the year; that the method of controlling these growths had not been satisfactory, and that the purification plant was not operated in an entirely satisfactory manner. It was accordingly recommended that the purification plant be operated at all times, that some necessary repairs be made, that copper sulphate be judiciously and regularly applied to prevent algæ growths and that consideration be given to the aeration of the supply as a means of removing the tastes and odors produced as a result of the decomposition of the organic matter in the reservoirs.

In a report upon the supply dated April 27, 1921, the following recommendations were made:

1. That greater care be taken in the operation of the purification plant particularly in the cleaning of the beds and the application of the alum.
2. That tests for color, turbidity and alkalinity be made by the operator at frequent intervals in order to keep a check on the operation of the plant.
3. That the chlorination apparatus be operated efficiently at all times.
4. That all unauthorized visitors be excluded from the premises.
5. That the rules and regulations for the protection of the supply be rigidly enforced.
6. That in order to keep down the growth of algæ in the reservoirs, vegetable growths be removed so far as possible and copper sulphate be applied in proper amounts at suitable intervals.
7. That consideration be given to the aeration of the water as a means of removing some of the tastes and odors produced as a result of the decomposition of the algæ growths in the reservoirs.

A reinspection of Lyons Public Water Supply, was made by Mr. Earl Devendorf on September 16, 1921.

The village authorities have applied copper sulphate frequently to the reservoirs, thereby preventing any large growths of algae. Some 35 pounds of powdered copper sulphate was applied broadcast over the lower reservoir on April 15, May 24, June 18, July 13, August 4, and September 3. Alum is used at the filter plant at the rate of approximately ½ grain per gallon and chlorine is applied at the rate of approximately .24 parts per million. In this connection, it was pointed out that it is advisable for the operator to make frequent tests for excess chlorine in the treated water by means of the starch determinations, in order that a sufficient amount of chlorine may be at all times applied to the water to insure the sterilization of the supply.

It was learned that the well at the New York Central car works formerly used for supplying water for drinking and culinary purposes in interstate traffic, has been discontinued for such use and is only used by the men at the shops. The water used for supplying the cars is now obtained from the village public water supply.

It was therefore recommended in a report dated December 31, 1921:

> 1. That the authorities in charge of the water supply continue their careful supervision and laboratory control of the operation of the purification plant in order to insure a water of safe sanitary quality being delivered to the consumers at all times.
>
> 2. That the authorities in charge of the water supply continue the frequent application of copper sulphate to the reservoirs in order to prevent the occurrence of algæ growths and the consequent objectionable tastes and odors in the public supply, and as previously recommended, consideration should be given to the aeration of the supply as a means of removing some of the tastes and odors resulting from the decomposition of the algæ growths in the reservoir.

MACEDON

At the request of the health officer of the village of Macedon, Mr. Earl Devendorf of this Department made an investigation of a proposed source of water supply for the village. It is proposed to dig a well, erect an electrically operated pumping station, lay mains and build a reservoir on a hill north of the village proper.

The site of the proposed well is in a pasture lot on a farm, the nearest farm buildings being some 500 feet distant. The well had been dug to a depth of some 7 feet and was about 7 or 8 feet in diameter. A small stream and pond were located about 75 feet from the well. Owing to the fact that the soil consists of sand and very coarse gravel which, under certain conditions, might allow infiltration from the stream, it was recommended that the well be located at a farther distance from the stream if possible. It was also pointed out that the well should be provided with a concrete curb and cover and that the area around the well should be fenced and that the pumping station be located away from the well so as to preclude the possibility of any pollution from this source. It was also pointed out that the reservoir should be covered to prevent the growth of algæ.

MADISON

A reinspection of the public water supply of the village of Madison, Madison county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department on December 7, 1920. A previous inspection of the supply was made by this Department in 1914 and a report thereon published in the Annual Report of the Department for that year.

Madison is located about 20 miles southwest of Utica and has a population of about 375, all of whom are served by the public water supply. The waterworks are owned and operated by the village and are under the control of a water board of which Mr. A. C. Bicknell is president.

The water supply is derived from springs located about 3/8 of a mile north of the village and is pumped directly into the distributing system, the surplus over the consumption going to a steel standpipe. The village has no sewerage system, the houses in general being served by cesspools.

A report on the prevous inspection recommended that adequate drainage ditches should be constructed to prevent surface wash from reaching the springs and that the standpipe should be covered in order to prevent algæ growths. From the recent investigation it appears that steps have been taken to prevent the entrance of surface wash to the springs but that the standpipe has not been covered.

In a report dated January 24, 1921 it was pointed out that the water supply was at the time of the inspection of a fairly satisfactory sanitary quality.

It was therefore recommended that the authorities in charge of the water supply continue to maintain the supply in a safe, sanitary condition.

MEDINA

A reinspection of the public water supply of the village of Medina, with special reference to the installation of a temporary hypochlorite sterilization plant, was made by Mr. Earl Devendorf, a representative of this Department, on September 1, 2 and 15, 1921. Previous inspections of this supply have been made in 1916 and 1920, and reports thereon will be found in the Annual Reports of the Department for these years respectively.

Medina is an incorporated village of some 6,500 inhabitants, located in the western part of Orleans county, about half way between the cities of Buffalo and Rochester. The village is served by a municipal sewer system which discharges without purification into Oak Orchard creek, a small stream flowing through the village and discharging through to Lake Ontario. The waterworks are owned by the village and operated under a board of trustees, of which Mr. H. Pettis is president and Mr. James Boyland is superintendent. The supply is obtained from a dug well located about 3 miles south of the village, from which it is pumped to a concrete reservoir. From the reservoir it flows by gravity to the village distribution system and a standpipe located in the village. Approximately 95 per cent of the population is served with the supply, and the maximum consumption is about 2,000,000 gallons per day, or 305 gallons per capita per day, of which it is estimated that 190 gallons are used for domestic purposes and 115 gallons for industrial use. In general the details of the waterworks system remain as described in the previous report.

The recent inspection was made as a result of a telegram received from Dr. George F. Rogan, health officer of Medina, informing this Department that the supply was running low, due to the long continued drought, and that the village would be obliged to pump canal water into the mains, and requested this Department to install a chlorination plant to treat the same. The Department communicated with Dr. Rogan by telephone on September 1 and obtained data as to the pumping equipment and other local conditions. He was advised that the emergency chlorination apparatus of the Department had just been installed at another place, but was requested, however, to have the village authorities refrain from pumping water from the canal, if possible, until a representative of this Department could reach Medina that afternoon to install the temporary hypochlorite sterilization plant.

Upon the arrival of our representative it was found that it had been necessary for the village to pump water from the canal, due to the extreme shortage of water and accompanying low pressure in the village. Pumping was started at 11 p. m. on August 31 and continued until 5:30 a. m. on September 2, 1921. With the aid of Mr. Boyland and his assistants, our representative installed a temporary hypochlorite plant over the suction well of the fire pump at the S. A. Cook furniture factory, which was being used to deliver the mixed canal and Oak Orchard creek water into the village distribution system. A solution of hypochlorite of lime was prepared in a 50-gallon barrel and the hypochlorite solution conveyed to the suction well near the intake pipe through a hose regulated by means of a control valve placed on the outlet pipe from the barrel. The application of the hypochlorite solution was regulated in accordance with the results of the starch iodide test for excess chlorine, directions for which were left with the operator. The emergency sterilization plant was started in operation at 9 p. m. in the evening. The pump used for delivering the water into the village distribution system consists of a steam pump having a rated capacity of 1,000 gallons per minute, and at the time of the inspection it was delivering approximately 800 gallons of water per minute.

During the evening our representative attended a meeting of the board of trustees and urged the village authorities to order immediately a liquid chlorine control apparatus for applying liquid chlorine to the water, inasmuch as such apparatus would be much more satisfactory than a crude hypochlorite plant such as that installed for emergency use. The village authorities were informed that the apparatus at the end of the period of pumping could be taken down and packed away for future need, when it would be immediately available. The board, acting upon the suggestion, ordered by telegram a Wallace and Tiernan manual control chlorinator. The apparatus was installed and placed in operation on September 4 by a representative of the Wallace and Tiernan Company.

In our previous reports it has been recommended that the village authorities engage the services of a competent water supply expert to aid them in augmenting the present public water supply, and that in case it becomes necessary to again pump water from Oak Orchard creek and the Barge canal overflow, before the supply is augmented by water from a satisfactory additional source, the water be first effectively chlorinated before it is pumped into the village mains, and that the present cross-connection between the fire pump at the furniture factory of the S. A. Cook Company and the village distributing mains be discontinued, or that double check valves be installed in an accessible manhole in accordance with the general plan approved by this Department.

From our recent inspection it appears that steps have been taken by the village to augment its supply as recommended, but the village authorities have not carried out the recommendations with reference to the cross-connection. Our representative was advised by the chief engineer of the S. A. Cook furniture factory that the connection between the village mains and the fire pump consisted of two gate valves between which an open standpipe was placed, and that the company considered this constituted a satisfactory safeguard against any possible entrance of polluted water into the village mains except at such times as required, due to the shortage of the village supply, when the supply would be chlorinated. In view of the fact, however, that the operation of the gate valves is dependent upon human control, there is always the inherent possibility of some one neglecting to perform the proper functions of operating these valves, and it would appear desirable to install the double check valves as previously pointed out, or to provide a severance of the two systems by removing a short section of the piping, which could be inserted in a few minutes at such times as might be necessary. It should, however, be given further study by the authorities in charge of the water supply, and the details of the piping system ascertained.

In a report upon the supply dated December 30, 1921, it was recommended:

1. That, in case it again becomes necessary to pump water from Oak Orchard creek and the Barge canal overflow to augment the regular well supply, the creek water should be sterilized by means of liquid chlorine applied in accordance with the results of the starch iodide test for excess chlorine, a copy of which is appended.
2. That the village authorities take steps as soon as possible to augment their present supply in accordance with the recommendations and suggestions of the engineer employed by the village to aid them in this problem.
3. That the village authorities ascertain the details of the cross-connection between the fire pump at the S. A. Cook furniture factory and the village distribution system, and give consideration to the separation of the two supplies by means of removal of a short section of the pipe line, which may be inserted in a few minutes at such times as it may be necessary to use this supply, or the installation of double check valves as previously recommended.

McKOWNVILLE

A reinspection of the public water supply of the village of McKownville was made by Mr. W. J. Erickson, sanitary inspector in this Department, on April 27, 1921. A previous investigation was made in 1919 and reported on under the name of Norwood on page 261 of the 40th Annual Report of the Department.

McKownville is an unincorporated village, with a population of about 250, located adjacent to the western boundary of the city of Albany on the western turnpike. It is a residential section and is not provided with a sewer system. The public water supply is owned and operated under the direction of Mr. W. H. Witbeck. It is derived from a small surface stream impounded in two small ponds on the north side of the state highway, a short distance west of the hamlet. From the lower pond the water is pumped by two hydraulic rams into a small concrete reservoir, from which it flows by gravity through mains.

The watershed above the point of intake has an area of about 1 square mile, with a total population of about 40. It is largely barren, rolling sandy area, with some pasturage and a small amount under cultivation. The streams are largely spring fed and flow in a fairly constant volume throughout the year. There are 8 houses, 1 church, 1 blacksmith shop and a cemetery on the watershed. Most of these places are located well back from the streams. There are, however, three places near the stream at which insanitary conditions exist. At one farm there is a privy not over 15 feet from the swampy area, where the springs feeding a tributary stream leave the ground. A small ditch has been dug from the rear of this privy to the swampy area, and a small slimy stream was flowing at the time of the inspection. About 300 feet above this was a pig pen containing about 6 pigs. The pen was about half full of stagnant water, which flowed a short distance in a ditch, whence it entered a tile drain which discharged into the swamp a short distance from the privy. A faint odor similar to that of sewage was noticeable in the vicinity. At the point where the small rivulets unite to form a small stream a duck pond has been formed by a small earthen dam. A short distance below and on the south bank of the same stream a privy is located on the bank about 75 feet from the stream. Near the head of another tributary stream is another farm. The privy at this farm is located on the bank 50 feet from the water's edge. This privy is provided with a tight container, which is drawn away and the contents buried in a field away from the stream. Chloride of lime is used as a disinfectant. The barnyard is about 150 feet distant from the stream, and cattle are allowed to drink from the stream. Beside the evident contamination from these sources, the supply is also subject to contamination from visitors, to whom the entire watershed is accessible. There are several well-worn paths in the wooded gullies which run close to the stream and cross it at several points. Ice is cut from this reservoir. From this inspection it appears that none of the previous recommendations made by the Department have been carried out.

In a report on an inspection of the supply dated May 11, 1921, the following recommendations were made:

1. That the owner of the supply make such arrangements with the owners of the property on the watershed of the reservoir as may be necessary, and remove all privies and other possible sources of contamination to a distance sufficiently remote from the stream and lines of drainage to prevent any danger of direct contamination.
2. That, should any difficulty be experienced in carrying out the above recommendation, application be made to this Department for the enactment of rules and regulations for the sanitary protection of the supply.
3. That the lower reservoir be fenced and trespassing thereon be prohibited.
4. That signs be posted on the watershed warning against contaminating the supply.
5. That the practice of ice cutting be permanently abandoned.

MOHAWK

An investigation of the public water supply of the village of Mohawk, Herkimer county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 13, 1921. Previous investigations of this supply were made in 1916 and 1918 and the reports thereon may be found in the Annual Reports of the State Department of Health for the years 1917 and 1918, respectively.

Mohawk is an incorporated village of some 2,700 inhabitants located in the southern part of Herkimer county on the Mohawk river opposite Herkimer. The village is served with a public sewer system, the sewage from which is discharged into the Mohawk river without treatment. The water supply is owned by the village and operated under a board of water commissioners, of which Mr. O. E. Day is president, Mr. F. D. DuBois is superintendent and Mr. George Rockerfeller is operator of the pumping station. The water supply is derived from a well located on the northeastern edge of the village between the West Shore railroad and the Erie canal. The water is pumped without treatment into the village distribution system and the excess over consumption goes to a standpipe located on a hill in the southeastern part of the village having a capacity of 70,000 gallons. The average daily consumption amounts to some 300,000 gallons or 112 gallons per capita per day.

The well from which the supply is derived is located approximately 200 feet north of the canal and about 75 feet from the West Shore railroad track. Originally the ground surrounding the well and pumping station was from 3 to 5 feet lower than the present ground surface, the surrounding area having been filled in to that depth. The soil below this filled material consists of some 3 or 4 feet of clay mixture forming an impervious layer, below which is a sand and gravel strata from which the supply is obtained. The well itself is 12 feet in diameter and 20 feet in depth. A steel casing is provided with an iron cover having a locked door. The water level in the well when the pump is not in operation is some 13 feet in depth or about 6 feet below the ground surface. When the pumps are in operation the water level is at a distance of approximately 12 feet below the ground level and is about 7 feet in depth in the well. It was stated that the water level will drop to this level within a period of approximately 30 minutes after the pumps are started. When the pumps are stopped the water will gradually rise up to the higher level within a period of about 1 hour. The berme bank of the canal is approximately 8 feet above the ground elevation at the well.

The recent inspection was made directly as the result of a communication from the health officer with reference to complaints of the village residents alleging the presence of tastes of gasoline and oil in the village water. At the time of the inspection the engineer was informed that these tastes and odors were detected by only a few residents on one or two streets in the village and that it lasted for only a short time. The question arose in the minds of the waterworks authorities in regard to the possibility of the pollution of their drinking water supply by wastes entering the well from the abandoned canal. The superintendent informed the engineer from this Department that during the winter time the section of the canal opposite the pumping station never freezes over, due to the continual spring flow at this point. It was thought that the oil or gasoline tastes and odors might be caused by the manufacturing wastes or other waste material discharged into the abandoned canal near the pumping station and at times of pumping that the water from the canal might be drawn into the ground water flow tributary to the well when the ground water level surrounding the well is known to be lowered. No definite information can be given in this matter, however, due to the fact that there are so many factors entering into the question which are at the present time unknown and the conditions at the time of the occurrence of these bad tastes and odors noted cannot be ascertained. While it is possible that such reversal of flow might occur in the ground water tributary to the well, it seems improbable. Inasmuch as the canal may possibly be abandoned in the future, it would seem advisable for the village to acquire at least that section of the canal opposite the well and pumping station when it might be filled in, thus eliminating any possibility of pollution of the ground water supply tributary to the well at this point. In the meantime the authorities in charge of the well should endeavor to carefully watch and give constant, careful supervision of the operating conditions of the well in order that any opportunities for pollution may be detected and eliminated.

The previous reports have pointed out that the water supply of Mohawk is derived from a source which should furnish a water of satisfactory sanitary quality if the wells are at all times adequately protected from pollution. It was, therefore, recommended that the authorities in charge of the supply should continue very careful supervision as in the past so that no insanitary conditions may occur to prevent the furnishing of a pure, wholesome supply.

In view of the above facts the following conclusions may be drawn:

1. That, as previously pointed out, the public water supply of the village of Mohawk is derived from a well which should furnish a public water supply of satisfactory sanitary quality so long as there are no in-insanitary conditions in existence near it; and was at the time of the inspection free from active contamination.

2. That the recent question of the pollution of the well supply from wastes being discharged into the canal water opposite the pumping station cannot be determined without some further knowledge of the conditions existing at the time of the occurrence of the tastes and odors.

In a report upon the supply dated June 21, 1921 it was recommended:

1. That the village authorities continue, as in the past, their careful supervision of the public water supply so that no insanitary conditions may arise in the vicinity of the well supply that will cause any possible pollution of the public water supply and that careful observation should be made of the ground water level in the vicinity of the well; together with the conditions of flow in the canal in order that any possibility of pollution from this source may be ascertained.

MONTGOMERY

An investigation of the public water supply of the village of Montgomery, was made by Mr. W. J. Erickson, sanitary inspector in this Department, on March 15, 1921. A previous inspection was made of this supply in 1916, the report upon which is found published on page 484 of the 37th Annual Report of this Department.

Montgomery, a village with a population of about 1,000, is located in the northern part of Orange county on the Wallkill river. There is no public sewer system in the village. Practically all of the population use the public water supply which is owned and operated by the village under the direction of a board of water commissioners of which Dr. E. Ross Elliott is president. The supply is obtained from a dug well located about ¾ of a mile east of the village center. From this well the water is pumped through a distribution system consisting of 4 miles of mains. The daily consumption averages 45,000 gallons. The supply from the dug well is occasionally augmented by pumping from two driven wells located north of the pumping station. In case of extraordinary draft on the supply such as during very severe fires, it is possible to pump direct from the Wallkill river. There has been no necessity for the use of this source during the past ten years, the wells being sufficient for the extra draft on the system caused by ordinary fires. When then used, warnings were issued, and the mains flushed out and the standpipe emptied and cleaned before the use of the well supply was resumed. The auxiliary wells are located about 100 feet from the dug well toward the state road. The supply is obtained by means of air lifts which raise the water to small concrete basins located over the wells from which it flows by gravity to the dug well. The wells are seldom used as the water derived from them has a disagreeable taste and odor. The well is located in a low area adjacent to a small brook. As the area tributary to this brook is sparsely settled it does not seem probable that the supply receives serious pollution from this source. The only house in the vicinity is 500 feet from it and on the opposite side of the state road. At the time of the inspection chickens were kept in the vicinity of the well and were allowed to roam freely around it. It seems therefore, that, particularly at times of heavy rains, surface wash enters the well carrying with it contamination from the chicken yard. The Wallkill river is badly polluted by municipalities along its banks above Montgomery. It seems probable that with the storage afforded by the standpipe, augmented by pumping from the well, any emergency can be taken care of without pumping from the Wallkill river.

In a report on an inspection of the supply dated April 4, 1921 the following conclusions were made:

1. That though the condition of the watershed is such that the wells should yield a satisfactory supply, it appears that some local pollution was entering the dug well and contaminating the water so that it cannot be considered to be of an entirely satisfactory sanitary quality.
2. That the surroundings of the pumping station are not in an entirely satisfactory condition particularly in regard to the keeping of chickens in the vicinity of the well.
3. That the use of the Wallkill river as an auxiliary source of supply is dangerous to the health of the community and the connection between the river and the village water system be severed and the source abandoned.

It was therefore recommended:

1. That the surrounding and interior of the pumping station and wells be maintained in a satisfactory sanitary condition.
2. That the water board make an investigation in order to determine the source of pollution and take immediate steps to eliminate it.
3. That the well casing of the dug well be banked with some impervious material so as to divert surface wash from its immediate vicinity.
4. That the cross-connection with the Wallkill river be permanently severed and that should there be any doubt as to the adequacy of the present supply a new auxiliary supply be developed.

MONTOUR FALLS

A reinspection of the public water supply of the village of Montour Falls, was made by Mr. W. J. Erickson, sanitary inspector, on April 12, 1921. Previous inspections were made of the supply in 1909 and 1917, the reports upon which are published in the Annual Reports of this Department for the respective years.

Montour Falls, which is a village of about 1,500 inhabitants, is located in Schuyler county on Catherine creek, the inlet to Seneca lake, 19 miles north of Elmira. No sewer system is provided although a few drains carry off surface water from the streets. About three-quarters of the population use the public water supply, which is owned by the village and operated under the direction of the board of trustees. The supply is derived from an impounding reservoir located in Johns brook at a point 2 miles northeast of the village. From this point the water is distributed by gravity through a distribution system consisting of about 6 miles of mains. A connection also exists whereby it is possible to augment the supply by gravity from Catlin Mill brook if occasion requires it. The supply is used principally for sprinkling and flushing purposes, the potable water being obtained from private wells. The public supply, however, is used by some for drinking and culinary purposes. The reservoir is formed by a concrete dam constructed across the narrow gorge of the creek.

The watershed tributary to the reservoir is about 3.68 square miles in area and has a total population of about 150. The area is very precipitous and largely wooded. The remainder is devoted to agriculture. About 30 farms are located on the watershed, all of which are located well away from the streams. Catlin Mill creek has a watershed of about 8½ square miles above the point of intake, with a population of about 625. The possibilities for contamination are considerably greater than in the case of the regular supply. The village of Odessa, with a population of about 350, is located about 3 miles upstream and undoubtedly to some extent pollutes the stream.

The private wells from which the water for domestic purposes is obtained are said to be largely of artesian character. The cesspools in the village are in general sunk into the first gravel stratum but do not penetrate the clay stratum. From the present inspection it appears that the previous recommendations have not been acted upon.

In a report on an inspection of the supply dated April 29, 1921 the following conclusions were made:

1. That the regular water supply of the village of Montour Falls is subject to contamination from the inhabitants and visitors on the watershed.
2. That the auxiliary supply is subject to a considerably greater amount of contamination from a populated watershed.
3. That though the majority of the private wells are thought to be furnishing a safe water, it is quite probable that pollution at times finds its way into these wells from the numerous cesspools and privies in the village.

It was therefore recommended:

1. That a modern purification plant be installed for treating the public water supply and put in operation without delay.
2. That pending the installation and operation of such a purification plant the water be sterilized continuously by the application of liquid chlorine.
3. That the auxiliary supply be abandoned and if it is necessary to obtain additional water, a new supply of safe sanitary quality be developed.
4. That the village authorities consider the matter of applying to this Department for the enactment of rules and regulations for the protection from contamination of the water supply.

MORAVIA

An investigation of the public water supply of Moravia, was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 16, 1920. A previous investigation of this supply was made in 1916 and the report thereon published in the 1916 Annual Report of the State Department of Health.

Moravia is an incorporated village of some 1,400 inhabitants, located in the southern part of Cayuga county, about 13 miles southeast of the city of Auburn. The village is located on the Owasco lake inlet. There is no public sewer system in the village, the sewage being taken care of by means of private cesspools and privies. The water supply is owned by the municipality and operated under the board of trustees, of which Mr. J. P. O'Hara is president. The supply is derived from springs located about 4 miles southeast of the village. From these springs the water flows by gravity to the village distribution system, the excess over the consumption being discharged into a storage reservoir located between the springs and the village. An auxiliary supply is obtained from a well located east of the village, from which the water is pumped into the distribution system when the flow from the springs becomes insufficient. The conditions surrounding the well are practically the same as described in the previous report. Since the reservoir has been repaired it has not been necessary to use this source of supply. At such times as the well was in use it was said that the pump was being operated practically throughout the 24 hours and that the amount of water pumped amounted to 115,000 gallons per day.

In a report on an inspection of the supply dated January 24, 1921, the following conclusion was made:

That, as previously pointed out and as confirmed by the recent investigation, the public water supply of the village of Moravia is of a fairly satisfactory sanitary quality.

It was therefore recommended that the authorities in charge of the public water supply continue their careful supervision of the conditions surrounding the springs and well and take every precaution possible to prevent any opportunity for pollution of the public water supply.

MORRISVILLE

A reinspection of the public water supply of the incororated village of Morrisville, Madison county, N. Y., was made by Mr. Earl Devendorf, a representative of this Division on November 23, 1921. Previous inspections of this supply have been made by this Division in 1917, 1918 and 1920 and the reports thereon published in the Annual Reports of the Department for the respective years.

Morrisville is a village with a present population estimated at 600 and is located about 16 miles south of the city of Oneida. Practically all of the inhabitants of the village are served with the public water supply. The waterworks are owned by the municipality and operated under the direction of the board of trustees of which Mr. Frederick Southworth is president and Mr. Jesse Parker is superintendent. The water supply is derived from a reservoir located about ¾ of a mile west of the village. From the reservoir water flows by gravity through the distributing system. The average daily water consumption is estimated at approximately 30,000 gallons a day or some 50 gallons per capita per day. Storage is provided by the above mentioned reservoir, the capacity of which is not known but may be roughly estimated to hold three months' supply of water for the village, as based upon the present estimated rate of consumption. In general the details of the waterworks system remain as described in the previous report.

The recent inspection was made as a result of word reaching this Department that the regular supply had been depleted due to the long continued drought and that it was necessary to pump water from an auxiliary supply, known as Jones pond. The Department at the request of the health officer, Dr. Chase, detailed a representative to visit the village with the Department chlorination apparatus. Due to the fact that the Department car became disabled however, it was impossible to take the apparatus to the village.

At the time of the inspection our representative accompanied by Dr. Chase visited Jones pond, proposed as an auxiliary source of supply for the village, and found that the village authorities had erected a pump, which was not in operation due to a breakdown in the tractor used in operating the pump. The pump had been operated on two occasions previous to the time of the inspection, said to be on November 15 for a period extending from 3 to 5 p. m. and on November 17 for a period from 3 p. m. until 9 a m. on the following morning. The pond is supplied by a small stream having a watershed of approximately ½ square mile in area and is fed mainly by springs within a very short distance above the pond. The pond, however, is subject to sources of pollution from two privies serving two houses located on property adjacent to and above the pond. The privies themselves are located on a very steep bank at a distance of approximately

75 feet away from and some 25 or 30 feet above the water. No vaults are provided for receiving the excreta which are discharged directly on the surface of the steep slope. At the time of the inspection the entrails of a hog which had been butchered on the day before, were observed lying on the ground surface at a point within 10 feet of the water. A large iron pot used for scalding the hog was also located on the ground nearby and, while it was empty at the time of the inspection, evidence was observed which indicated that the scalding water had been discharged on the surface of the ground immediately above the water.

The above insanitary conditions were pointed out to Dr. Chase and to the other members of the Water Board later at a meeting at the store of Mr. Frederick Southworth, president of the board of trustees at which meeting there were also present Mr. Jerry C. Blair, Mr. Jesse Howlett, trustees; Mr. Solon Frank, street commissioner, and Mr. Jesse Parker, superintendent. They were advised that the Department could not approve of the use of water from this pond without satisfactory treatment or effective sterilization by means of liquid chlorine. They were also advised to immediately notify Mr. Russell Suter, senior assistant engineer of the waterpower commission that the village intended to use the Mill pond supply as an auxiliary to their regular water supply. They were further advised that upon the approval of the waterpower commission it would be advisable for the village to request the enactment of rules and regulations by this Department for the sanitary protection of the supply and that the present insanitary conditions noted above could be remedied by carefully patrolling the land surrounding the pond in order to prevent the reoccurrence of butchering on the area near the pond and by providing watertight concrete vaults under the privies which should then be cleaned frequently and the contents removed and disposed of at a point remote from the watershed and not likely to cause any possible pollution of the supply. The use of hypochlorite of lime in connection with the operation of the pump for sterilizing the supply was taken up with the village authorities.

The Department was later informed that due to subsequent rains the reservoir had filled and it had not been necessary to resort to the use of the Jones pond supply. Should it be necessary however, to again use this supply, precaution should be taken to improve the sanitary conditions on the watershed and to provide for the sterilization of the supply before being delivered to the consumers.

The watershed tributary to the main supply consists of about 60 acres, consisting of uninhabited agricultural ground. No direct sources of pollution were found to exist on the watershed but opportunities for indirect pollution of the supply by surface wash from the highway north of the reservoir may at times reach the supply through the lack of proper maintenance of the ditch provided for diverting this surface wash. At the time of the inspection this ditch was partly filled with dead weeds and limbs. This material should be cut and removed and the ditch maintained in a clean condition in order that no surface wash may back up and overflow the land leading to the reservoir. In our previous reports it has been recommended that the village authorities continue a careful supervision of the sanitary conditions of the reservoir and watershed and that copper sulphate be applied to overcome the algæ growth. At the time of the recent inspection it was stated that no serious trouble had arisen from the presence of algæ growths occurring in the reservoir.

In a report upon the supply dated December 29, 1921, it was recommended:

1. That the authorities in charge of the public water supply continue to maintain a careful supervision of the sanitary conditions existing on the watershed above the reservoir and maintain the diverting ditch free from weeds and other foreign matter in order that any surface wash may not reach the reservoir and cause any possible pollution of the supply.

2. That should it become necessary to resort to the use of Jones pond the sanitary conditions on the watershed be improved as outlined in the body of the report above.

3. That in case any trouble is experienced in carrying out these recommendations and in removing any objectionable conditions found to exist on the watershed, the village authorities apply to this Department for the enactment of rules and regulations for the sanitary protection of the watershed, provided for under the provisions of the Public Health Law.

4. That before the water from Jones pond is delivered to the public mains it should be sterilized with hypochlorite of lime or liquid chlorine in the manner outlined in the body of the report and an excess of chlorine be maintained at all times in accordance with the results of the starch iodide tests, a copy of which is attached.

5. That the village authorities continue to apply copper sulphate at frequent intervals in order to eliminate any objectionable tastes and odors in the public water supply resulting from the presence of algæ growths in the reservoir.

MOUNT MORRIS

A reinspection of the public water supply of the village of Mount Morris, Livingston county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on December 10, 1920. A previous inspection of the supply was made by this Department in the year 1917 and a report thereon published in the Annual Report of the Department for that year.

Mount Morris is located in the western part of Livingston county, about 40 miles southwest of Rochester. The present population has slightly decreased in the past few years and amounts to 3,300. Of the total population all are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of the board of water commissioners, of which Mr. Charles Bingham is president. The water supply is derived from Silver lake, located about 8 miles west of Mount Morris, and flows by gravity through a conduit under pressure to mechanical filters, and from them to the distributing reservoir located in the western part of the village. From the reservoir the water flows by gravity through the distributing system. The average daily water consumption is approximately 500,000 gallons.

Since the last previous inspection changes to the supply have been made in the following particulars: A Wallace & Tiernan solution feed chlorine apparatus has been installed in duplicate, housed in a small wood partitioned room at the filter plant. The apparatus formerly provided for the application of hypochlorite of lime to the filtered water has been abandoned. Silver lake is approximately 3 miles long and about one-half a mile wide, having an average depth of about 25 feet. The northern half of the eastern shore line for about a mile is thickly populated in the summer. This community consists of Fairview, with a population of about 250; Walkers and Silver Lake Assembly, with a population of 1,000. The winter population for the community on the lake shore does not amount to more than possibly 100 people. The largest settlement on the west shore is the Country Club, with about 15 or 20 houses. The northern section of the shore within the village limits of Perry is about five-eighths of a mile in length and some 600 to 800 feet in width. Numerous cottages are built closely together along streets parallel to the lake. No sewers have been constructed for the lake district. The Silver Lake Assembly has no sewerage system, but it is provided with a large cesspool to take care of the sewage. No cesspools are allowed to be constructed unless they are over 300 feet from the lake shore. The village of Walkers disposes of its sewage mostly by disinfection and uses the Kaustine system. Fairview, in the town of Castile, is provided with privies, most of which have removable containers. There are in all about 400 to 500 houses on the east shore of Silver lake, south of the village district of Perry. It is estimated that of these houses 75 per cent are provided with privies having removable containers, some of which are of the Kaustine type, 2 per cent are provided with cesspools, and the remainder with privies. South of the Assembly there are only 4 or 5 cesspools. Several barns having large manure piles were noticed and, while located on a precipitous slope, are probably outside of the limited distance provided by the rules and regulations, but the storm water from these districts, polluted by the drainage from a few privies, manure piles and surface wash, reaches the lake quickly over the steep slopes leading to the water. An inspection is made yearly of the lake district by the local authorities in charge of the Perry water supply to detect possible sources of pollution to the lake. Ice is cut every year about 200 feet north of the water intakes by the Silver Lake Ice Company, which employes a large number of horses and men for about 2 months during the year. The horses are driven on the ice, but the manure is scraped off as fast as it accumulates. This winter, however, it was learned that the ice company intends to cut ice by the use of a gasoline cutter, and it is thought that the use of horses will be decreased.

The filter plant consists of 2 New York Continental Jewel pressure mechanical filters, operating at a rate of 141.6 million gallons per acre per day. A solution feed Wallace & Tiernan chlorinating apparatus, No. 3976, is installed. The chlorine is applied to the raw water just before it enters the filters at a rate of about .26 parts per million. A duplicate apparatus is provided for use in case of emergency. A gas mask is also accessible. The reservoir shows evidence of growths of green algæ. No chemical treatment is used to free the water of algæ. The reservoir is not covered. The reservoir is situated on high ground, and its outer walls are about a foot above the ground surface, precluding the possibility of surface water entering the water supply. The reservoir is inclosed by a high fence having at its top 3 rows of barbed wire.

The village is provided by a sewerage system and a sewage treatment plant, which consists of a 2-story tank, which takes care of about 65 per cent of the population, the remainder being taken care of by private systems and old privies. The effluent from the tank is discharged without further treatment through a tile pipe into the tail race of the mill, a tributary to Canaseraga creek. From the recent investigation it appears that the previous recommendations of this Department have been carried out.

In a report on an inspection of the supply dated February 8, 1921, the following recommendations were made:

1. That the authorities in charge of the water supply continue to exercise their careful supervision over the operation of the water plant.
2. That the treated water be frequently tested for excess chlorine, in accordance with the instructions issued by this Department, and the rate of application of the chlorine regulated in accordance with the results of this test.
3. That the reservoir be repaired so that it may be cleaned when necessary.
4. That the authorities consider increasing the capacity of the filtration plant in order that a lower rate of filtration may be maintained.
5. That alum be used at all times.

NAPLES

A reinspection of the public water supply of the village of Naples, Ontario county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on April 22, 1921. Previous inspections of the supply were made by this Department in 1913 and 1916, and the reports thereon published in the Annual Reports of the Department for those years.

Naples is located 30 miles southwest of the city of Geneva, and has a population estimated at 1,100, about 90 per cent of which are served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners, of which Mr. D. H. Maxfield is president. The water supply is derived from Reservoir creek, about 2 miles south of the village. The water flows by gravity into the distribution system.

The watershed tributary to the supply is approximately 3.1 square miles in area and is used largely for agricultural purposes. It is possible that drainage from farm houses may at times reach the supply.

The village owns about 4 or 5 acres of land 2½ miles northwest of the village, on which are located 3 undeveloped springs known as the Boals springs. The village authorities have contemplated developing the springs as a source of water supply in preference to the present surface supply. Although the springs are situated in swampy ground, they are said to give a constant flow of water, and if properly developed should provide a satisfactory source of water supply. The largest spring is located in a wooded area and the other two springs are located in an open strip of land, on which a number of cattle are pastured, and considerable pollution from this source may reach the springs. It is possible, however, to eliminate this source of pollution by properly protecting the springs. The village authorities also intend to construct a reservoir between the springs and the village.

In a report dated May 16, 1921, the following recommendations were made:

1. That the village authorities obtain a new water supply by properly developing and protecting the Boals springs, or, in case the development of that source is found impracticable, by protecting the present water supply by the enactment of the rules and regulations and the installation and operation of a modern purification plant.
2. That the development of the Boals springs or the installation of a modern purification plant to treat the present water be carried out under the supervision of a competent engineer.
3. That, pending the development of the springs or the installation of a modern purification plant, a chlorinating apparatus be installed and the present supply treated continuously by the application of a proper amount of liquid chlorine.

NEWARK

A reinspection of the public water supply of the village of Newark was made by Mr. Earl Devendorf, a representative of this Division, on September 14, 1921. Previous inspections of this supply have been made by this Division in 1913, 1918 and 1921, and the reports thereon issued in the Annual Reports of the Department for the respective years.

Newark is an incorporated village with a present population estimated at 7,000 and is located in the southern part of Wayne county, approximately 50 miles west of Syracuse. The village is partly sewered with a separate system of sewerage, the sewage from which is discharged in the Canardus creek, after treatment in the disposal plant consisting of Imhoff tank sprinkling filter and final settling tank. Of the total population practically all are served with the public water supply. The waterworks are owned and operated by the municipality under the direction of the municipal board, of which Mr. Stanley Scarth is superintendent. The water supply is derived from Case creek on which an impounding reservoir and filtration plant has been constructed some 8 miles south of the village of Newark. The water flows by gravity through the filter plant to the village distribution system, consisting of some 17 miles of water mains. The consumption varies from 350,000 to 400,000 gallons per day throughout the winter season and is increased to between 600,000 and 700,000 gallons per day during the summer. Of the above amount the Commonwealth Chemical Company are using on an average of 50,000 gallons per day. Storage for the purified water is provided in an open distributing reservoir located on a hill just west of the village. The details of the purification plant and the waterworks system remain in general as described in the previous report.

The watershed area above the storage reservoir is approximately 7 square miles and consists mostly of farm land having a total population of about 250. Rules and regulations for the sanitary protection of the public water supply of Newark were enacted by this Department during the past year. At the time of the inspection the water in the storage reservoir was at a very low level, due in part to the long continued drought of the past summer, and in part to the serious leaks which have developed through the bottom of the reservoir. The village authorities had a pump in operation pumping water through a fire hose on the upper side of the reservoir near the point where the leaks are said to have developed in such a manner as to stir up the silt on the bottom. It is hoped by this method to deposit silt and mud over the coarse material and fill up the interstices in such a manner as to prevent the escape of the water. Alum was being used to coagulate the water before filtration, at an average rate of 1.2 grains per gallon. This amount of alum appeared to be giving a satisfactory flock. The aerator on the inlet to the coagulation basin was out of service, due to the low level of the water in the reservoir, the head not being sufficient to operate the aerator. As a result of the recent inspection it appears that the authorities in charge of the supply have in part carried out the previous recommendations. The authorities are endeavoring to maintain a strict sanitary patrol of the watershed and have provided equipment and chemicals necessary for making the simpler tests of the raw and treated water, and have had analyses made of the water on a number of occasions during the past year in order to determine the efficiency of the operation of the plant.

Chlorination apparatus had not as yet been installed at the time of the inspection.

The results of the examination of the filtered water made by the Division of Laboratories and Research show no reduction in color and turbidity. The reduction of the organic matter as measured by the albuminoid ammonia and oxygen consumed is 87 per cent and 33 per cent respectively. The results of the bacteriological examination show somewhat high total counts which may likewise be affected by the delay in transit.

In a report on an inspection of the supply dated December 27, 1921, the following recommendations were made:

1. That the authorities in charge of the supply continue their careful supervision of the public water supply of Newark, including frequent and careful sanitary patrols of the watershed, daily tests to determine the necessary amount of alum to be applied, frequent local analyses of the supply in order to determine the efficiency of the operation of the plant and the keeping of a careful record of the estimated amount of water treated and the amount of alum applied.
2. That the authorities in charge of the supply should provide the necessary apparatus for measuring and recording the flow of water through the plant in order that the proper rate of application of alum may be more easily and readily ascertained.
3. That the spring located north of the Nichol Block be abandoned and the use of this water for drinking and culinary purposes discontinued.

NEWBURGH

A reinspection of the public water supply of the city of Newburgh, was made by Mr. W. C. Emigh, assistant engineer in this Department, on June 3, 1921. Previous inspections of this supply were made by this Division in the years 1909, 1914 and 1917 and reports thereon published in the Annual Reports of the Department for those years.

Newburgh, a city with a population, according to the 1920 census, of 30,366, is located in Orange county on the west bank of the Hudson river. Nearly the entire population is served with water from the public supply. The waterworks are owned and operated by the municipality under the direction of a city manager. The water supply is derived from several streams, the waters of which are impounded in a reservoir known as Washington lake reservoir, located about 2½ miles west of the center of the city. From this reservoir the water is delivered by gravity to about two-thirds of the population of the city. The remainder of the city obtains its water from the high service system to which the water is pumped. The average daily consumption is said to be 399,000 gallons or about 130 gallons per capita.

The watershed tributary to the Washington lake reservoir is 8.8 square miles in area and consists of a moderately well populated farming district. Continuous care is exercised by the waterworks officials of the city to prevent, as far as possible, the pollution of the water supply. The privies on the watershed are of a sanitary type with tight vaults which are cleaned by the removal and burial of the contents at regular intervals. The watershed is inspected by Mr. Wolvern of the waterworks department each month. There are two main streams tributary to Washington Lake reservoir, both of which have been diverted from their natural courses at short distances above the reservoir and flow through artificial paved channels to the reservoir. In some places the streams pass through pasture land and the cattle are permitted to wade and stand in the streams. Washington Lake reservoir floods an area of 160 acres. In addition to the Washington Lake reservoir there is a smaller reservoir known as the Lockwood basin. Two small brooks flow into the basin. Water is drawn from this reservoir periodically, as may be desired, or necessary to prevent waste of water over the spillway.

The water supply is treated with chlorine which is applied by means of a Venturi control dry feed chlorinator of the Wallace and Tiernan type. The chlorine is applied in the main leading from the reservoir to the city distribution system. At the time of the inspection the compensator valve had been removed and returned to the manufacturer for repairs and the chlorinator was being operated without the automatic control and at as constant a rate as possible. The operator stated that under these conditions 18 pounds of chlorine are used per day, but that when the automatic control equipment is in operation the average application of chlorine is about 16 pounds per day, or a rate of 0.5 parts per million. Although the city distribution system is of the gridiron type, as previously noted, there are, in effect, a number of dead ends resulting from the separation of the upper service and lower service by valves. Trouble has been experienced with tastes and odors in the water supply. It has been customary to treat the water in the reservoir at such times with copper sulphate, and this treatment has been generally successful. The quantity of water available has, during times of extended drought, proved insufficient for the requirements of the city. To augment the supply it has been necessary on one or more occasions for the city to purchase water from the city of New York. The purchased water has been obtained from the Catskill aqueduct which passes over the Washington Lake watershed. Plans were prepared for the development of an additional source of supply and an application for approval of same was filed with the State Conservation Commission on December 30, 1919. After consideration of the plans they were rejected by the Commission.

In a report on an inspection of the supply, dated June 20, 1921, the following recommendations were made:

1. That the careful supervision of the watershed be continued.
2. That an additional unit for the treatment of the water with chlorine be installed and that both the new unit and the present unit be maintained in operating condition at all times.
3. That the water be treated with chlorine at all times in sufficient quantity to secure satisfactory disinfection of the water, as shown by the starch iodide excess chlorine test.
4. That consideration be given by the city authorities to the question of installing a modern filtration plant.

NEW ROCHELLE

A reinspection of the public water supply of the city of New Rochelle, Westchester county, N. Y., was made by Mr. Alfred Mullikin of this Division, on August 12, 1921. A previous inspection of this supply has been made by us in the year of 1913 and a report thereon published in the Annual Report of the Department for that year.

New Rochelle, a city with a present population of about 38,000, is located 17 miles north of the Grand Central station in New York City. Of the total population practically all are served with water from the public water supply. In addition the villages of Bronxville, Tuckahoe, North Pelham and Pelham Manor, a part of the town of Eastchester are furnished with water from this supply. The waterworks are owned and operated by the New Rochelle Water Company, of which Mr. Columbus O'Donnel Iselin is president. The water supply is derived largely from Hutchinson creek and Troublesome brook. There are 4 reservoirs maintained in connection with the water supply. The watersheds of the supply are traversed by numerous highways. The watershed of Hutchinson creek is traversed by numerous highways but is sparsely populated, and there appears to be no direct source of pollution in the vicinity of the reservoirs other than surface wash from the roads and fields due to heavy rains. The watershed area of Troublesome brook, however, contains numerous houses which frequently give rise to pollution to this source of supply.

The previous recommendations of this Department, in regard to applying for a revision of the rules and regulations to include streams and reservoirs on the Troublesome brook supply, in regard to connecting houses near reservoir No. 2 to the sewerage system and in regard to sterilizing the water supply with hypochlorite of lime, have been carried out.

In a report, dated September 7, 1921, on an inspection of the supply, the following conclusions were drawn:

1. That the water supply furnished by the New Rochelle Water Company is of a fairly satisfactory sanitary quality.
2. That the authorities in charge of the public water supply have carried out the previous recommendations of this Department.
3. That a careful sanitary patrol is maintained over the watershed to see that the rules and regulations enacted by this Department for the protection from contamination of the supply are carried out.

It was therefore recommended:

1. That the authorities in charge of the public water supply make a careful inspection of the watershed furnishing water to the gravity system to locate and eliminate, if possible, all sources of pollution.
2. That the authorities in charge of the public water supply pay particular attention to the sterilization of the gravity supply and apply sufficient hypochlorite of lime to properly sterilize the supply at all times.
3. That daily tests be made for excess chlorine in the treated water in accordance with the instructions issued by this Department, and the rate of application of the hypochlorite of lime be regulated in accordance with the results of these tests.

NEW YORK CITY

An investigation of the sanitary quality of the water supply of the city of New York was made, with a special reference to the question of certification by the United States Public Health Service for use for drinking and culinary purposes by interstate carriers. Inspections were made during the year 1921 and information was furnished by the Department of Water Supply, Gas and Electricity of the city of New York.

The city of New York is located at the southern extremity of the State and occupies the counties of New York, Kings, Bronx, Queens and Richmond. The city is divided into five boroughs, the names and boundaries of which are identical with those of the counties, excepting that New York county is called the borough of Manhattan, and Kings county the borough of Brooklyn. The population of the city is estimated at about 6,000,000, of whom 5,600,000 are served with water from the municipal supply and the remainder with water furnished by private water companies, one in Brooklyn, and the other in Queens. These companies are the Flatbush Water Works Company, in Brooklyn, and the Citizens Water Supply Company, the Urban Water Supply Company, the Jamaica Water Supply Company, the Woodhaven Water Supply Company, the Queens County Water Company, and the Montauk Water Company in Queens. The total water consumption of the city is about 660,000,000 gallons per day or 109 gallons per capita per day. There are 3,014 miles of cast-iron water mains varying in size from 66 inches to 4 inches in diameter, on which there are about 387,000 service taps, 106,000, or 36 per cent, of which are metered. A minimum of 30 pounds per square inch is set for the water pressure in Manhattan, although in many places the pressure reaches 65 pounds per square inch. The pressure in the other boroughs averages about 40 pounds per square inch. The municipal water supply is maintained and operated by, and the private water supplies are under the supervision of, the board of water supply, gas and electricity of the city, of which Nicholas J. Hayes is commissioner; John J. Dietz, deputy commissioner; Merritt H. Smith, chief engineer; and William W. Brush, deputy chief engineer.

The city is served by a system of combined sewers discharging into the waters of the Hudson and East rivers and New York bay at a large number of places.

The municipal supply is derived mainly from the Catskill (Esopus) watershed, the Croton watershed, and the Byram and Bronx watersheds. Some water is, however, taken from the wells on Staten Island and from the Brooklyn supply on Long Island, and it is understood that it will be necessary to continue the use of these two supplies until the completion of the work which will make the water from the Schoharie watershed available.

The Catskill supply available at the present time is that from the Esopus creek watershed. This shed covers an area of 257 square miles and its minimum yield as developed is estimated at 250,000,000 gallons per day. The present draft on this source of supply is about 375,000,000 gallons per day. The watershed is for the most part sparsely populated, a large part of the area being hilly and wooded. There are, however, several villages and hamlets on it and considerable land in the valleys is under cultivation. The density of population on the shed is estimated at about 30 persons per square mile.

The water is collected by an impounding dam across Esopus creek, at Olive Bridge, forming what is known as the Ashokan reservoir. This reservoir has a surface area of 12.6 square miles, an average depth of 50 feet, an available capacity of about 127,700,000,000 gallons, and a surface elevation of 590 feet above mean sea level. From the reservoir the water is conducted to the city distribution system by an aqueduct 120 miles long, terminating in Silver Lake reservoir of the borough of Richmond. The time of transit through this aqueduct, not including storage in the several reservoirs connected to it, is estimated at 3 days. From the Ashokan reservoir to the Kensico reservoir at Valhalla, a distance of about 75 miles, the aqueduct is designed to carry a little over 500,000,000 gallons per day. The larger part of the conduit is constructed of concrete and built in cut and cover. It is generally of horseshoe cross-section, 17 feet high and 17 feet 6 inches wide. The section, however, varies with the topography and character of the ground. In tunnels the section is 17 feet high and 13 feet 4 inches wide, and in pressure tunnels the form is circular and varies from

11 feet to 16 feet 7 inches in diameter. The Moodna Breakneck tunnel, which carries the water under the Hudson near Cornwall, is of this type, 14 feet in diameter, and passes under the river at a depth of 1,114 feet. In crossing valleys steel pipe siphons, consisting in general of 3 pipes, 9 to 11 feet in diameter, are used. All of these pipes have not yet been constructed, which limits the capacity of the aqueduct at the present time to about 375,000,000 gallons per day.

At Valhalla the Catskill water is discharged into the Kensico reservoir, which has been constructed at the site of the old reservoir formerly used to collect the water from the Bronx and Byram watersheds. This reservoir has a surface area of 3.5 square miles, an average depth of 52 feet and an available capacity of 30,570,000,000 gallons, the equivalent of about 50 days supply. Its normal surface elevation is 355 feet above sea level. The Kensico reservoir also receives water from the watersheds of the Bronx and Byram rivers, which cover an area of about 22 square miles and yield on the average approximately 18,000,000 gallons per day. The density of population on the watershed of these two rivers is about 25 persons per square mile. Most of the houses are located well back from the reservoir. A 10-foot circular concrete by-pass is provided by which the water may be conducted directly to the city without passing through the Kensico reservoir.

From the Kensico reservoir the aqueduct continues for a distance of 17 miles to the Hillview distributing reservoir in Yonkers just north of the city line of New York. This reservoir has a capacity of 929,000,000 gallons. Its surface elevation is 295 feet which determines the pressure of the Catskill water supply in the city. From this reservoir the city pressure tunnel varying from 15 to 11 feet in diameter, extends through the Bronx and the full length of Manhattan and under the East river to a shaft in Brooklyn from which a 68-inch steel pipe extends north to Queens and a 48-inch cast-iron pipe extends south through the Bay Ridge district of Brooklyn to 79th street where it connects to the 36-inch flexible pipe laid under the Narrows to Richmond. Here the line terminates in Silver Lake reservoir, a reservoir of 438,000,000 gallons capacity with a surface elevation of 228 feet.

In order to measure the flow of water through the aqueduct, 3 Venturi meters have been installed 1 near the Ashokan reservoir, 1 above the Kensico reservoir and 1 below the Kensico reservoir.

Catskill water is at present being used principally to supply Brooklyn, Queens, Richmond and the higher parts of Bronx, to which places it can be conducted without pumping although it is necessary to pump a small amount of the Catskill water in Richmond and the 3d ward in Queens to supply certain high districts. Part of the supply is available for use in the business section of Manhattan. In Richmond the Catskill supply is supplemented by water from the wells at the Grant City station and in Brooklyn by water pumped from the old Brooklyn supply.

The Catskill water supply is protected by rules and regulations enacted by the commissioner of water supply, gas and electricity of New York City and approved by the State Department of Health on February 1, 1917, and the board of water supply, gas and electricity of the city maintains a uniformed force in the shed to enforce these rules and regulations and to protect the supply from contamination. As a further protection the water of the Esopus creek, through which most of the runoff of the watershed reaches Ashoken reservoir, was treated with chlorine at Boiceville. The amount of chlorine used has until recently been about 0.11 of a part per million parts of water.

The water is aerated to remove to some extent tastes and odors which may develop and is treated with liquid chlorine to destroy any pathogenic bacteria it may contain. The aerators are located just below the Ashokan and Kensico reservoirs and are similar in design, each consisting of a basin some 250 by 500 feet in size and each containing some 1,800 vertical nozzles so formed as to throw the water into the air in the form of a spray. In addition to the chlorination of the stream entering the Ashokan reservoir the entire Catskill supply is treated with liquid chlorine in the screen chamber below the Kensico reservoir. Chlorine has been applied during the first part of 1921, in the proportion of about 0.05 of a part per million.

Chemical and bacteriological examinations of samples of the water taken daily at certain points and weekly at other points, are made at the laboratories of the Board of Water Supply, Gas and Electricity. The average figures for the year 1920 are given in the following table:

	Ashokan reservoir outlet	Kensico outlet, chlorinated	Tap, Queens	Tap, Brooklyn	Tap, Richmond
	Daily	*Daily*	*Weekly*	*Daily*	*Weekly*
Turbidity	3	2	2	2	2
Color	10	8	7	7	8
Odor	lv.	lv.	lv.	lv.	lv.

B. Coli, 10 c.c	21	4	19	21	29

Figures for B. Coli are percentages of positive results.

Water from the Schoharie watershed which is adjacent to the north side of the Esopus shed, will not be available for several years. This shed has an area of 314 square miles and an estimated yield of about 250,000,000 gallons per day. The water will be collected by an impounding reservoir formed by the construction of a dam across Schoharie creek at Gilboa. The surface area of the reservoir will be 1.8 square miles, the average depth 58 feet and the available capacity 20,000,000,000 gallons. The surface elevation of the reservoir will be 1,130 feet. A tunnel under the Shandaken range of the Catskill mountains 18 miles long and 10 feet 3 inches by 11 feet 3 inches in cross section will conduct the water from the Schoharie reservoir to the Esopus creek at Allaben where the water will flow in the creek channel for 11 miles to the west end of the Ashokan reservoir. Work on the development of this source of supply is now being carried on by the board of water supply of the city of New York and it is estimated that the work will be completed by 1924.

The Croton water supply is derived from a watershed having an area of about 375 square miles covering the eastern half of Putnam county and a large district in the northeastern part of Westchester county. A large part of the area is used for agricultural purposes and there are several villages and hamlets on it. The density of population is about 50 persons per square mile. In addition to the surface water from this area the supply also receives the treated sewage from Brewster and Mt. Kisco. The water from the shed is collected in 6 controlled lakes and 10 sewage reservoirs, the lowest and largest of which is the Croton reservoir formed by the construction of a dam across the Croton river about a mile above Quaker bridge. This reservoir has a surface elevation of 200 and a capacity of 33,800,000,000 gallons. The total storage capacity of all reservoirs and lakes on the shed is about 104,000,000,000 gallons. As developed the minimum yield is approximately 336,000,000 gallons per day and the average yield about 400,000,000 gallons per day.

Two aqueducts about 35 miles long conduct the water from the Croton reservoir to the city. One of these, known as the old Croton aqueduct, follows along the east side of the Hudson river to Yonkers where it turns eastward through Bronx and crosses the Harlem river at and by means of High bridge, and continues to the Central Park reservoir. This aqueduct is of horseshoe cross section 8 feet 5 inches high and 7 feet 5 inches wide except in the city where portions of it have been replaced by cast-iron pipe. It has a capacity of about 90,000,000 gallons per day. Its total length is 38.1 miles. The other aqueduct, known as the New Croton aqueduct, tunnels through the hills and takes a more direct course to the city, lying in general several miles east of the old aqueduct. It passes under the Harlem river in a pressure tunnel 300 feet below sea level and terminates at the 135th street gate house from which the water is carried by eight 48-inch cast-iron pipes to the old aqueduct, the distribution system and the Central Park reservoirs. Through the first 25 miles of its 33 miles of length the aqueduct is of masonry construction, horseshoe shaped in cross section, 13 feet 6 inches by 13 feet 6 inches in size, except across Gould's swamp where it is depressed and is circular in form, 14 feet 3 inches in diameter. At the end of this portion of the aqueduct near Van Cortlandt park it is connected with the Jerome Park receiving reservoir. This portion of the aqueduct has a capacity of 300,000,000 gallons per day making the total capacity of the 2 aqueducts between the Croton reservoir and the city, about 390,000,000 gallons per day. From the Jerome Park reservoir to the terminal gate house at 135th street, a distance of a little less than 7 miles, the aqueduct is constructed as a pressure tunnel 12 feet 3 inches in diameter except in the Harlem river siphon where it is 10 feet 6 inches in diameter. Below the 135th street gate house the water is conducted in eight 49-inch cast-iron pipes as noted above.

The Croton water is used in portions of Manhattan and Bronx and is distributed to certain sections below about 40 feet in elevation from the Jerome Park reservoir, the 136th Street gate house and the Central Park reservoirs. For certain higher districts it is pumped at the stations located at 79th street and Harlem river and at 98th street and Columbus avenue and at certain times at the Jerome Park pumping station in the Bronx. The quantity of water pumped is between 65,000,000 and 100,000,000 gallons per day.

The Jerome Park reservoir has a capacity of 773,000,000 gallons and a surface elevation of 134 feet. The Central Park reservoirs have a total capacity of 1,205,000,000 gallons and a surface elevation of 119 feet. In addition to these reservoirs there are the High Bridge reservoirs of 11,000,000 gallons capacity with a surface elevation of 218 feet, the High Bridge standpipe with a surface elevation of 336 feet. The 98th Street standpipe with an elevation of 229 feet and the Jerome Park standpipe with an elevation of 320 feet, which are used in connection with the pumping station.

The entire supply of water from the Croton shed is chlorinated at Dunwoodie where the chlorine has been, during the first part of 1921 applied to the water at an average rate of about 0.13 of a part per million. In addition to this, several polluted streams on the Croton watershed are treated with chlorine. The effluent from the sewage disposal plant at Mount Kisco consisting of settling tanks, contact beds and sand filters, is treated with 15 parts per million of chlorine. The sewage of Brewster is treated with 400 parts per million of chlorine. Katonah brook at Katonah is treated with 3.3 parts per million. The Kisco River below Mount Kisco is treated with 1.6 parts per million. Lake Glenida at Carmel is treated with 0.2 parts per million. Tonetta brook at Brewster is treated with 2.06 parts per million.

As in the case of Catskill, daily and weekly samples are taken at different points and analyzed at the laboratories of the department of water supply, gas and electricity of the city. The average results of these analyses for 1920 are given in the following table:

	Croton lake outlet	Aqueduct at Dunwoodie, chlorinated	Tap in Manhattan
	Weekly	*Daily*	*Daily*
Turbidity	2	2	2
Color	17	15	14
Odor	1 veg.	1 veg.	1 veg.
	Weekly	*Weekly*	*Weekly*

The old Brooklyn supply now held in reserve and used to some extent to supplement the Catskill and Croton supplies, is derived from streams, wells and infiltration galleries lying on Long Island in the district between Brooklyn and Amityville. The total area of the watershed tributary to this supply is approximately 168 square miles. The infiltration galleries about 6 miles long at a depth of from 10 to 15 feet, yield about 40,000,000 gallons per day. The driven wells of various depths from 30 to several hundred feet yield approximately 60,000,000 gallons per day. The total dependable yield of the shed is about 150,000,000 gallons per day. The quality of the gallery and well waters has generally been considered satisfactory for use without treatment except that if drawn on too heavily the water from some of the wells becomes brackish. The water of the surface supply is chlorinated. There are 27 pumping stations arranged to take water from the different surface supplies and deliver it through a system of pipes including a 72-inch steel main extending from Massapequa to the main pumping station at Ridgewood which lifts the water to the Ridgewood reservoir, the surface elevation of which is 172 feet and the capacity 300,000,000 gallons. This reservoir is located on a hill where there are few passers-by and protected from trespassing by an iron railing. The reservoir is now used in connection with the Catskill supply as well as to receive water from the Brooklyn supply. Certain high level districts in Brooklyn are furnished with water by additional pumping in connection with the Mount Prospect reservoir and the Mount Prospect tower. The elevation of the former is 200 feet and its capacity 19,000,000 gallons. The elevation of the latter is 280 feet.

Water from this Long Island shed may also be used in the third ward of Queens. There are three standpipes of comparatively small capacity located in this district. The Flushing standpipe having an elevation of 221 feet, the College Point standpipe having an elevation of 192 feet and the Whitestone standpipe having an elevation of 181 feet.

The following is the average of the results of analyses of water from the Brooklyn supply taken at the Ridgewood pumping station during 1920:

Turbidity	2	Chlorine	5.8
Color	6	Hardness	21.0
Odor	1-v.	Alkalinity	6.0
Free ammonia	0.028	Iron	0.31
Albuminoid ammonia	0.008	Bacteria per c.c., 37° C	35
Nitrites	0.001	B. Coli, 10 c.c	Absent
Nitrates	0.30		

In Richmond the water supply was formerly obtained from several groups of wells connected to these pumping stations. These wells were capable of yielding about 15,000,000 gallons per day. Two small reservoirs and a standpipe in addition to the Silver Lake reservoir were used in connection with this system. The main station at Grant City with its walls is now used to supply water to supplement that delivered to Silver Lake reservoir by the Narrows siphon, the capacity of which is only equivalent to about two-thirds of the water consumption of the island.

The average results of the weekly analyses of samples from the Grant City wells, from which most of the supply is being taken at present, during 1920 are as follows:

Turbidity	1	Hardness	183
Color	4	Alkalinity	105
Odor	0	Iron	0.15
Free ammonia	0.010	Bacteria per c.c, 37° C	53
Albuminoid ammonia	0.008	B. Coli, 0.1 c.c	0
Nitrites	0.000	B. Coli, 1 c.c	0
Nitrates	2.41	B. Coli, 10 c.c	5
Chlorine	47.2		

In the Boroughs of Brooklyn and Queens there are several private water companies which derive their water from local wells and furnish a total of about 40,000,000 gallons per day to a population of some 400,000 persons.

In Brooklyn the Flatbush Water Works Company supplies about 13,000,000 gallons per day to the 29th ward.

In Queens the private water companies are as follows:

The Citizens' Water Company supplies a little over 12,000,000 gallons per day to the 2nd ward.

The Urban Water Supply Company supplies about 1.3 million gallons per day to a small section of the 2nd ward.

The Woodhaven Water Supply Company supplies about 3.25 million gallons per day to the 4th ward.

The Jamaica Water Supply Company, about 6½ million gallons per day to a part of the 4th ward.

The Queens County Water Company supplies about 3¼ million gallons per day to the 5th ward.

Broad Channel Corporation supplies about 20,000 gallons to a small part of the 5th ward.

The Montauk Water Company, owned by the Long Island railroad, furnishes about 2,000,000 gallons per day, practically all of which is used by the railroad company.

The results of analyses of the water from the more important of these supplies, during 1920, are given in the following table:

All the water supplies of the city are under the supervision of the Department of Water Supply, Gas and Electricity which keeps a force of about 40 inspectors on the watersheds to protect them from contamination and maintains three laboratories, one at the Ashokan gate house, one at the Mt. Kisco gate house and one at the Mt. Prospect reservoir, Brooklyn. Daily bacteriological examinations are made of samples of water taken at 17 points on the system and weekly and monthly examinations of samples of water taken at other points.

The question of the filtration of the water supply of the city has been considered and provision for the installation of filters made near the Catskill aqueduct. No definite steps have, however, been taken toward the installation of such a plant.

All the railroads entering New York City use water from the public supply of the city for drinking and culinary purposes on their trains; and since section 13 of the Interstate Quarantine Regulations requires that water provided for drinking or culinary purposes on railroad cars engaged in interstate traffic shall be from a source which is certified and approved as producing a water of satisfactory sanitary quality and safety, and it is the custom of the U. S. Public Health Service to base such certifications on information furnished by the State Health Boards, it has become necessary for the State Commissioner of Health to examine into the suitably of the water supply for use for drinking and culinary purposes in interstate traffic. The results of analyses of the water as given in the above tables seem to indicate insufficient protection from contamination or the application of too small amounts of chlorine.

For the purpose of discussing the matter conferences were held at the office of the State Department of Health in New York City on April 15th and July 8th, 1921. At the April 15th conference there were present: Dr. Matthias Nicoll, Jr., Chairman; Dr. A. B. Wadsworth and Mr. Theodore Horton, representing the State Department of Health and Dr. W. H. Park and Dr. F. E. Hale, representing the City of New York.

At the July 8th conference there were present: Dr. Herman M. Biggs, State Commissioner of Health; Dr. Matthias Nicoll, Jr., Deputy State Commissioner of Health; Mr. Theodore Horton, Chief Sanitary Engineer of the State Engineer's Office; Mr. C. M. Sheehan, Deputy Commissioner of Water Supply, Gas and Electricity, City of New York, N. Y.; Wm. W. Brush, Deputy Chief Engineer, Department of Water Supply, Gas and Electricity; Dr. F. E. Hale, Chemist, Department of Water Supply, Gas and Electricity; Dr. J. A. Shears, Sanitary Expert of the Department of Health of the City of New York, and Mr. Sol Pincus, Associate Engineer, U. S. Public Health Service.

At the meeting on July 8 a full discussion was had and opinions expressed with reference to general and specific sources of contamination of protective and corrective measures carried out in previous years and at the present time, of laboratory analyses of the various sources of supply by the city and state laboratories, and the coordination of these data and conditions with the typhoid fever records of the city. Although different opinions were expressed by those present with reference to the effectiveness of corrective and protective measures employed by the city to render the water supply safe against not only general but incidental and unusual sources or acts of contamination of the Catskill and Croton watershed, all were agreed that the only proper course for the city to assume in this regard is to take every possible precaution and provide every possible safeguard, within reasonable limits of cost, that is necessary for the full protection of this supply.

It was therefore generally agreed by those present, and accepted as a precedent to the certification of the satisfactory quality of the supply by the United States Public Health Service, that the following program be carried out:

1. To install at Pine Hill, Phoenicia, Katonah and at other points on the watersheds of the Catskill and Croton supplies where the pollution is most concentrated, sewage disposal systems and plants like the one now being installed at Chichester.

2. To improve the method of application and distribution of chlorine to the stream flow, the chlorination plant now being operated on the Esopus creek just above its point of entrance to Ashokan reservoir, using chlorine in amounts that will give an excess of 0.1 of a part per million by the ortho-tolidin test.

3. To establish chlorination plants, so far as it is practicable, at the outlets of all open reservoirs not effectively protected against access by land area and by man proof fences. These points to be determined after investigations by representatives of the State Department of Health and the Department of Water Supply, Gas and Electricity.

4. With reference to the proper amount of chlorine which should be applied for the disinfection of the water supply:

   (a) Apply continuously at all points of application on the system except on the Esopus creek above referred to, chlorine in quantities sufficient to give an excess of 0.1 part per million, is determined by the ortho-tolidin test, and never less than 0.2 parts per million. This procedure to be followed pending results of tests outlined below.

   (b) Institute at once and continue for at least a period of one year daily or weekly tests as may be mutually agreed upon at one main chlorination plant on the Catskill supply and at one on the Croton supply in order to determine the optimum quantity of chlorine necessary for bacterial removal and avoidance of residual chlorine odors, such tests to include the determinations stated below, the amount of chlorine to be applied in each case in four different amounts namely, 50 per cent, 75 per cent, 100 per cent, and 120 per cent of the amount necessary for complete absorption of organic matter, using the 5 minute contact, and collection of samples to be taken after 5, 15 and 30 minutes period of contact (that is for bacteriological results and such other chemical results as practicable).

      1. Turbidity.
      2. Color.
      3. Albuminoid ammonia.
      4. Oxygen consumed.
      5. Dissolved oxygen.
      6. All odors, including the odors of chlorine, microscopical organisms and secondary odors resulting from chlorine.

7. Chlorine.
8. Kjeldahl nitrogen.
9. Total counts on gelatin.
10. Total counts on agar.
11. B. Coli 3 dilutions.
12. Other determinations as experience may suggest.

(c) From the study of the above results carried throughout one year, showing the variation in range of the quality of these waters and the results of application of chlorine under the different methods and conditions of application to determine more definitely a procedure or system of application of chlorine which will give optimum results, that is, highest bacterial efficiency with safe margin or a factor of safety in the avoidance of residual odors in the waters as delivered to the consumers, due consideration to be given to direction and residual chlorine odors.

(d) In connection with these tests to run a series of control tests showing definitely the relation and efficiency of the orthotolidin and the starch iodide tests for practical operation and control, giving attention to color, temperature and other conditions which might affect the result.

5. Where present laboratory tests are not being carried out in strict conformity with the standard methods as adopted by the American Public Health Association that such methods be adopted either as a substitution or at least in addition to the present methods of technique.

In accordance with this agreement orders were issued by the Department of Water Supply, Gas and Electricity of the city on and before July 28, 1921, that the quantity of chlorine applied to the water at Kensico, Dunwoodie and Brooklyn should be such as to give an excess of 0.1 of a part per million of free chlorine in the treated water and that the minimum dose should be 0.2 of a part per million.

On August 19, 1921, most of the distributing reservoirs of the city were visited for the purpose of observing possible sources of pollution and determining the feasibility of protecting the reservoirs from incidental pollution by excluding access to the reservoirs by man proof fences or by chlorinating the supplies at the outlets from the reservoirs.

Hillview reservoir, the main distributing reservoir for the Catskill supply is located on a hill with side slopes in all directions, but with a level strip on top of the embankment on which there is a walk and driveway. A heavy woven wire fence about 8 feet high surrounds the reservoir at the top of the inner slope of the embankment and inside of the walk and driveway. Since the public has access to the area outside of the fence line during both day and night there is obviously danger of incidental pollution by visitors who frequent the location in considerable numbers particularly on Sundays and holidays. There is no patrol of the grounds around the reservoir other than the occasional visits of the men who operate the gates. At the time of the inspection there were some 300 to 500 seagulls on and above the water of the reservoir. No systematic effort has been made to exclude these gulls. The representatives of the city thought that there would be considerable opposition to the exclusion of the public from the area around the reservoir. For this reason it seems that chlorination of the water as it leaves the reservoir would probably be the more expedient method of protecting the supply. This could be accomplished, it was learned, by transferring the chlorination plant from the Kensico reservoir and arranging it to apply chlorine at the outlet gate house of the Hillview reservoir. When this is done a patrol of the reservoir should of course be established to prevent so far as possible pollution of the water in the reservoir.

Williams Bridge reservoir is fed by Catskill water from Kensico, but is used only in case of emergency. The reservoir is on a hill with steep slopes and is surrounded by two fences, one at the bottom of the embankment and one on the coping around the reservoir. The most practical method of protecting this reservoir would seem to be the reconstruction of the fence at the bottom of the embankment so as to make it man proof and the exclusion of the public from the ground around the reservoir. Chlorination might be used if found necessary to protect the reservoir from pollution by seagulls.

Jerome Park reservoir is the main distributing reservoir for the Croton supply. On one side of this reservoir there is a high wall and embankment on the other side a steep embankment at the bottom of which there is a fence. The wall and embankment on the first side are practically man proof, but the fence on the other side is not. The public is not permitted to use the grounds around the reservoir, but boys and other unauthorized persons trespass upon them at times. No attempt is made to prevent seagulls from reaching the reservoir. The best method of protecting this reservoir appears to be the substitution of a man proof fence for the present fence and the removal of all brackets or projections from the wall so as to make it impossible to scale it. In addition to this, a regular patrol of the grounds should be established to prevent any possible trespassing and to keep away the gulls.

The old Central Park reservoir is located in Central park and is fed by water from the Croton supply. It is protected by a low fence and the regulations prohibit the public from trespassing near it. It would seem desirable that a man proof fence be constructed around this reservoir and a patrol maintained to effectively exclude all trespassers.

The new Central Park reservoir, the larger of the two in Central park, is located practically adjacent to the old reservoir. It is accessible to the public by the paths which extend along the top of the embankment, and is protected only by an easily scaled fence on the coping of the wall which surrounds the reservoir near the top of the inner slope of the embankment. Considerable opportunity for incidental pollution obviously exists. It is understood that from two to five persons drown in this reservoir each year. In view of the fact that the public would probably object to the erection of a man proof fence a hundred feet back from the edge of the water and the prohibiting of trespassing inside of the fence, it appears that the better method of protecting the supply from this reservoir, if found practicable, would be to chlorinate the water at the points where it leaves the reservoir and to substitute a higher fence less easily scaled than the present one.

The High Bridge reservoir is an equalizing reservoir which takes the surplus from the 179th street pumping station connected with the Croton supply and discharges it into the distribution system again through the same pipe when the demand requires. The reservoir is protected by two fences, one at the top and the other at the bottom of the embankment, but the fences are not man proof and trespassers obtain access to the reservoir. The best method of protecting the reservoir would obviously be to replace the present fence with man proof ones and maintain a patrol on the grounds.

The Ridgewood reservoir in Brooklyn receives water from the Catskill supply and the Brooklyn supply. It is surrounded by low, easily scaled fences. There seems to be no reason why this reservoir cannot be satisfactorily protected by the construction of a man proof fence at the bottom of the embankment and the establishment of a suitable patrol.

The Prospect reservoir, which is supplied with water from the Catskill supply, is surrounded by a steep embankment at the top and bottom of which are iron fences. The reservoir could be easily protected by making the fence at the bottom of the embankment man proof and establishing a suitable patrol.

Silver Lake reservoir, in the borough of Richmond, is the terminus of the aqueduct from the Ashokan reservoir. The ground around the reservoir is used for park purposes and is protected only by a fence similar to the one at the Hillview reservoir. Owing to the fact that objection would probably be made to the erection of a man proof fence and the exclusion of the public from the area around the reservoir, it appears that it would be best to resort to chlorination to protect the water of this reservoir. A patrol should of course be established to protect as far as possible the reservoir from incidental pollution by possible trespassers.

The Clove reservoir, in the borough of Richmond, is surrounded by a fence which is only five or six feet away from the edge of the embankment.

and the public has access to the grounds around the reservoir up to the fence. The use of the grounds around this reservoir as a park is unimportant and the erection of a man proof fence seems to be the most practical method of protecting the water.

On August 18, 1921, Woodland, Phoenicia and Chichester were visited for the purpose of examining into the manner of the disposal of the sewage from those places with special reference to the pollution of the city's water supply.

At Chichester a sewerage system is being installed by the city of New York and the disposal plant with the exception of the tanks has been practically completed. It is expected that the system and plant will be completed in the near future. When completed and put in operation the system and plant will correct the insanitary conditions formerly existing at this place.

Woodland is a summer colony and consists of a hotel, several cottages and a boys' camp. It is served by a sewerage system that discharges into a series of cesspools the effluent from which flows into Woodland creek, a tributary of Esopus creek. At the time of the inspection this effluent was comparatively clear. An analysis by the laboratory of the department of water supply, gas and electricity indicates considerable dilution but little oxidation. The substitution of a modern filtration plant for the present system of cesspools would seem desirable.

Phoenicia, with a population of almost 500, has a public water supply and no sewerage system. The village is served principally by cesspools, and there are practically no drains or overflows which lead directly into the creek. The soil is, however, coarse and gravelly and undoubtedly considerable very poorly purified sewage finds its way to the stream. One or two cesspools were overflowing at the time of the inspection and it is understood that it is necessary to dump the contents of one of the hotel cesspools into the gutter at frequent intervals in order to avoid flooding the cellar. Since the village has a water supply and since conditions will undoubtedly become gradually worse and more difficult to correct, it seems advisable that a sewerage system and sewage disposal be installed as soon as practicable.

Pine Hill was visited on July 7, 1921. The summer population of this village is some 2,000 persons. Numerous sources of pollution of Esopus creek exist in the form of overflowing cesspools, drains and ditches, and it is understood that there are some 18 or 20 points of pollution in the village. A sewerage system and sewage disposal works should obviously be constructed in this village without delay.

On August 18, 1921, Boiceville was visited and the method of applying chlorine to the Esopus creek and the condition of the creek with reference to the more effective application of the chlorine inspected. The present plant is arranged for the application of chloride of lime but is to be replaced in the near future by a plant of the solution feed type for the application of liquid chloride. The flow exceeds 500,000,000 gallons per day only for 5 per cent to 10 per cent of the time, and it is proposed to treat the flow up to this volume with sufficient chlorine to give an excess of 0.1 of a part per million. The creek at this point is quite variable in width and irregularly filled with boulders which divide the flow into unequal and ununiformed channels. In order to satisfactorily apply the chlorine it would seem necessary that the flow should be concentrated into a width of from 40 to 50 feet by diverting dams so constructed as to allow no leakage. The chlorine should be applied at points about 5 feet apart across this restricted area. It is understood that Mr. Wheeler will work out plans along these lines.

The matter of the scope and technique of the laboratory work to be carried on in connection with the analyses mentioned above was discussed with Dr. Hale on August 17 and 18, 1921.

It was generally agreed that the same work should be carried on for both the Croton and Catskill supplies, that for the Croton supply being done at Dunwoodie and that for the Catskill at Kensico or at Hillview in case the chlorinating plant is moved to the latter place. The samples of raw waters are to be examined for turbidity, color, odors, including the direct and secondary odors due to chlorine and microscopic organisms, albuminoid ammonia, Kjeldahl nitrogen, chlorine, oxygen consumed, dissolved oxygen, total counts on gelatin (2 determinations); total counts on agar (2 determinations); B. coli, 3 dilutions, with bile. The examination of the treated water is to comprise: Determinations of counts on gelatin and agar, and of B. coli as well as albuminoid ammonia, chlorine and Kjeldahl nitrogen, of the raw water to which chlorine has been applied in the following percentage of complete absorption of organic matter, namely 50 per cent, 75 per cent, 100 per cent, and 125 per cent, using in each case 4 different periods of contact with chlorine, namely: 5 minutes, 15 minutes, 30 minutes and 1 hour.

In reference to the determination of free chlorine it would seem best that a series of tests be run to compare the relative merits of ortho-tolidin and starch iodide. This is important because while ortho-tolidin is generally considered the more sensitive it has under some conditions failed to give uniform and reliable results.

In general the analyses should be made in accordance with the "Standard Methods of Water Analyses" of the American Public Health Association. Since, however, the laboratories of the city use the green bile media for the B. coli test there seems to be no objection to the use of this media for the routine work provided sufficient tests are made in accordance with the "Standard Methods of Water Analyses" to determine the relation between the results given by the 2 methods. Generally the use of 3 dilutions in the test for B. coli would seem advisable. The method used by the U. S. Public Health Service might however be employed at intervals in order to establish a standard of comparison between the 2 methods.

On October 11, 1921, the sanitary conditions of the Croton watershed, giving particular attention to the conditions at Bedford Hills, Brewster, Carmel, Katonah, Patterson, Pawling and Mt. Kisco, were inspected.

Bedford Hills is an unincorporated village of about 1,500 population. It has a water supply but no sewerage system, privies and cesspools being in general use. Many of the houses are located on the hills sloping toward the tributary of Croton lake which flows through the village so close to the stream that there is considerable danger of contamination of its water. It is understood that the city intends to chlorinate the water of this stream at a point near Katonah, although such a chlorination plant has not yet been established. It would seem advisable that a sewerage system and sewage disposal plant should be installed in this village.

Brewster, a village of about 2,500 inhabitants, is located on the east branch of the Croton river, one of the tributaries of Croton lake. The village has a municipally owned water supply. There is no comprehensive sewerage system although about 15 per cent of the population are served by a small system, the sewage from which is disposed of by chlorination and subsurface irrigation. The wastes from a cheese factory and some incidental sewage pollution enters one of the small streams passing through the village. This stream is passed through a crude roughing filter before reaching the reservoir. The city prepared plans for a sewerage system and sewage disposal plant for this village several years ago, but no steps have been taken toward the installation of the system or plant. It would seem very important that the sewerage system and sewage disposal plant for this village should be installed and put in operation with as little delay as possible.

Carmel, a hamlet of about 600 population, is located on Glenida lake, the water of which is chlorinated at the outlet of the lake before it reaches the reservoir about 25 miles away. There is no public water supply except that the city furnishes water to the school and some 30 houses. There is no general sewerage system. Some 8 or 10 houses have sink drains which discharge into the gutters, and a number of houses on Main street have sink drains which discharge on the ground not far from the edge of Glenida lake. A seminary, having a population of about 200, located at Carmel, has its own sewage disposal system. Representatives of the city seem to be of the opinion that the installation of a sewerage system and sewage disposal plant for this hamlet is not urgent. Since, however, the sewage might be readily conducted to a point not on the watershed of the Croton supply it would seem desirable that the sewerage system and sewage disposal plant be installed and the sewage disposed of at such a point.

Katonah, with a population of 1,000, has a water supply furnished by a private water company, but no sewerage system. There are some 8 or 10 special cases of contamination in the village and a considerable number of places where cesspools are located so near the stream as to make contamination of it probable. The installation of a sewerage system and sewage disposal plant at this place is desirable.

Patterson is an unincorporated village of about 850 inhabitants, located some 38 miles above the inlet of the Croton water supply. There is no public water supply and no sewerage system in the village. The distance from the intake and the local condition make the installation of a sewerage system and sewage disposal works less urgent than in many of the other villages on the shed, but it would seem desirable that the installation of such a system and works be given consideration.

The village of Pawling, with its population of 1,000, about 100 of which are on the watershed of the Croton water supply, is located some 40 miles above the intake at Croton lake. There is a public water supply but no general sewerage system. Owing to the distance of this village from the intake the danger of contamination is not as great as from the villages near to Croton lake. In view, however, of the nature of some of the pollutions and the fact that a sewerage system and sewage disposal plant would be simple to provide, it would seem desirable that they be installed.

The village of Mt. Kisco, with a population of 4,000, is provided with a sewerage system and a sewage disposal works, consisting of settling tanks, contact beds, sand filters and a chlorination plant.

Yorktown Heights is an unincorporated village of some 400 inhabitants scattered over a considerable area. There is no water supply and no sewerage system. The conditions are such that the installation of a sewerage system and sewage disposal plant does not seem urgent at present, providing a careful supervision of the conditions is maintained by the city and the rules and regulations for the protection of the supply strictly enforced.

In general it may be said that sewerage systems and sewage disposal plants should be installed at Bedford Hills, Brewster and Katonah without delay; that at Carmel, Patterson and Pawling the installation of sewerage systems and sewage disposal plants is not so urgent and the conditions might be controlled by careful house to house inspections and the enforcement of the rules and regulations, and that at Yorktown Heights the installation of a sewerage system and sewage disposal plant is not urgent at present provided the rules and regulations for the protection of the water supply are strictly enforced.

In a report upon the supply dated December 8, 1921 the following recommendations with reference to the Croton and Catskill supplies were made:

1. That chlorination plants at Boiceville, Dunwoodie, Kensico (or Hillview), Old Central Park Reservoir, and at points on the Croton watershed where plants are now established, be continued in operation.
2. That pending results of special laboratory tests referred to below, the amounts of chlorine applied to the water at all chlorination plants shall be in such amounts as will give an excess of not less than 0.1 part per million as determined by the ortho-tolidin test, and be in amounts of never less than 0.2 parts per million.
3. That if found practicable to install the necessary apparatus, and to apply chlorine in the amounts stated above in Recommendation No. 2, without objectionable physical results, the point of application of chlorine be changed from Kensico to the outlet of Hillview reservoir; otherwise that it be retained at Kensico and the public excluded from the vicinity of Hillview reservoir by the establishment of a man-proof fence appropriately placed.
4. That man-proof fences be constructed around Williams Bridge reservoir, Jerome Park reservoir (except where stone wall exists), Old Central Park reservoir, High Bridge reservoir, Ridgewood reservoir,

Prospect reservoir and Clove reservoir, and otherwise such sanitary patrol established as will effectively prevent access of the public to these reservoirs.

5. That at the New Central Park reservoir a new fence, higher and less possible to scale, be constructed to take the place of the present old low fence; and if found practicable, to apply chlorine to the outlets of this reservoir in amounts not less than those stated in Recommendation No. 2; that chlorination plants be established at these outlets to treat all water leaving this reservoir, otherwise that the public be excluded entirely from the vicinity of this reservoir by a man-proof fence constructed at least 50 feet back from the edge of the reservoir.

6. That the public be excluded by means of properly constructed fences and patrol measures from the area surrounding the aerators below the Ashokan and Kensico dams.

7. That systems of sewerage and sewage disposal be installed without delay at Pine Hill, Phoenicia and Woodland on the Esopus creek and at Bedford Hills, Brewster and Katonah on the Croton watershed; and that at Carmel, Patterson and Yorktown Heights effective sanitary patrol and enforcement of rules and regulations be maintained to prevent so far as practicable the pollution of the Croton supply.

8. That laboratory tests be carried on at once at Dunwoodie and Kensico (or Hillview) and continued for a period of at least one year in order to establish a more intelligent, systematical and effectual control over application of chlorine to the water of the Catskill and Croton supplies.

9. That said tests shall include the following analyses of samples of both raw and chlorinated water covering the following determinations:

(a) Samples of raw water to be tested for turbidity, color, odors (including direct and secondary odors due to chlorine and microscopic organisms), albuminoid ammonia, Kjeldahl nitrogen, chlorine, oxygen consumed, dissolved oxygen, total counts of gelatin (two determinations), total counts on agar (two determinations), B. Coli (three dilutions using bile).

(b) Samples of treated water to be tested for counts on gelatin and agar, B. coli albuminoid ammonia, chlorine and Kjeldahl nitrogen of the raw water to which chlorine has been applied in the following percentage of complete absorption of organic matter, namely, 50 per cent, 75 per cent, 100 per cent and 125 per cent, using in each case four different periods of contact with chlorine, namely, 5 minutes, 15 minutes, 30 minutes and one hour.

10. That in performing these tests laboratory technique shall in general be in accordance with the "Standard Methods" except that green bile media may be used for the determination of B. coli as routine procedure if several tests are made in accordance with the "Standard Methods" to determine the relation between results from the two methods.

11. That if in the determination of free chlorine ortho-tolidin is used as an indicator there will also be used at intervals starch-iodide as an indicator in order to show the relative merits of these two indicators.

12. That at the chlorination plant at Boiceville chlorine gas be substituted for "bleach," and in order to accomplish a better and more uniform diffusion of the gas to the water, a low dam of watertight construction be constructed to concentrate the flow into a width of not over 40 feet to 50 feet with the chlorine applied at points of not over 5 feet apart across this restricted area.

13. That the Department of Water Supply, Gas and Electricity furnish, if convenient, the State Commissioner of Health and the U. S. Public Health Service, monthly or quarterly as may be desired, with the results of laboratory tests outlined above.

14. That if the above recommendations are promptly and effectively carried out that the U. S. Public Health Service issue favorable certificates to interstate carriers which use the Catskill and Croton supplies for drinking and culinary purposes.

NEW YORK CITY (Randall's Island — House of Refuge)

A special investigation of the water supply of the New York House of Refuge at Randall's Island, New York City, was made by Mr. W. C. Emigh, assistant engineer in this Department, on April 14, 1921.

Samples of the water supply collected in the past including those collected at the time of general investigations of the sanitary condition of the institution, have indicated the presence of some pollution in the supply. The recent special investigation was made in an effort to obtain further details of the institution water system and, if possible, to determine whether or not the pollution reached the supply subsequent to its entrance into the institution mains.

The water supply for the New York House of Refuge is furnished by the city of New York. A 10-inch connection extends from the city main on 119th Street under the East river to Randall's Island upon the southern portion of which the institution buildings are located. At a point on the grounds a short distance from the sea wall the main is deflected approximately at a right angle and continues southerly a short distance to a point from which two 4-inch mains extend in an easterly direction to the south wing of the main building. Both of the 4-inch mains extend from that point southerly to the power house, one outside of the wall of the main building and one within the building. These two 4-inch mains furnish the supply for the fire pumps at such times as it may be necessary to use the pumps. A third 4-inch line extends from the 10-inch main at a point near the first deflection easterly nearly to the Administration building from which point it branches in two directions. One branch extends in a northerly direction to the north wing of the main building in which are the officers' quarters. The second branch extends in a southerly direction to the power house through which it continues to the Primary building.

In addition to the connection with the city supply described a 10-inch main extends from 121st Street to the Children's Hospital which is located on the northerly portion of the Island. A connection exists between the water systems of the hospital and of the House of Refuge. This connection normally is closed by a valve and is reserved for emergency use only.

A fire supply is provided which is intended to be entirely separate from the service supply. For the fire supply three wood stave tanks are installed in the domes of the main building. The tank in the center dome has a capacity of 10,000 gallons, that in the northerly dome a capacity of 9,000 gallons and that in the southerly dome a capacity of 2,000 gallons. The last tank is out of repair and not in use. The principal main of the fire system extends in a northerly and southerly direction through the main building, the power house and the primary building. Risers extend from the horizontal main with hose connections on the several floors. These risers also extend to the tanks already described and serve as the source of supply for them.

A riser enters each of the tanks through the bottom and is fitted with a "T" just inside the tank. On the horizontal branch of the "T" is fitted a check valve which permits water to pass from the tank into the riser but prevents the flow of water through it into the tank. The riser continues vertically to an elevation somewhat below the top of the tank at which point it is fitted with a float valve through which the supply reaches the tanks. An overflow is provided from each tank leading to the roof of the building. The tanks are open and birds enter the domes in which they are located.

The main pipe line of the fire system enters the power house on the north side and continues through it to the primary building located on the south. In the power house there are two connections between the fire system and the service system of the institution each fitted with a check valve to prevent water passing from the former to the latter. As these are single check valves there was no convenient way for our engineer to test the tightness of the valves. There is always a possibility, however, in the use of check valves that they may not be entirely watertight.

In addition to the main connections there is in the power house a ¼-inch pipe extending from the fire system to the service supply. From this small pipe a connection extends a few inches to a pressure gauge. On each side of the gauge connection is a valve. Our engineer found that both of these valves were open. Upon closing the valve on the fire system side the gauge registered 20 pounds representing the pressure on the service side at that point. The valve on the service side was then closed and the one on the fire system side opened when the gauge registered 26 pounds.

It thus appears that at the time of the inspection the pressure was greater in the fire system than on the service system and that a flow of water from the former to the latter occurs through the small cross connection when both valves are open as was said to be the usual condition. It is to be noted that the pressure varies considerably during the hours of the day and night and that in some cases there is undoubtedly a flow in the opposite direction. At the time of the inspection the water level in the largest tank was about 10 inches below the apparent high water mark and in the tank located in the dome of the north wing, and farthest from the power house, the difference in the two levels was somewhat less. Although the ¼ inch pipe connecting the two systems under a 6-pound difference of pressure would admit of only a comparatively small flow, such flow would, in the course of a number of hours, aggregate a considerable quantity. While it is not possible to state definitely that any part of the pollution in the water evidenced by previous analyses has reached the system in this way it is within the range of possibility that such is the case.

In regard to the variation of pressure at separated points of approximately equal elevation throughout the buildings caused by the draught upon the line it was found that at approximately the same time the pressure in the toilet located in the main rotunda was 32 pounds and the pressure in the main kitchen was 20 pounds. It is thus evident that the sizes of pipes throughout the institution are such that a variation of draught caused a considerable fluctuation in pressure.

At the time of the investigation bacteriological samples of the service water supply at several points in the building, the fire supply from the open tank, and the New York City water supply at 119th street were collected and forwarded to the New York City branch of the Division of Laboratories and Research for analyses.

The bacteriological examinations of the seven samples collected during the years 1915 to 1920 inclusive have shown the presence of intestinal bacteria in 62 per cent of the 10 c.c., 14 per cent of the 1 c.c. and 19 per cent of the 1/10 c.c. inoculations. Examinations of the 5 samples collected at the time of the recent investigation all showed a low total count and the presence of intestinal bacteria in none of the inoculations. These last analyses point to no pollution of the supply at the time of sampling. It is to be noted, however, that occasional examinations of a water supply at infrequent intervals form a somewhat unsatisfactory basis upon which to judge the quality of the water. It would, therefore, be advisable that at least 4 times each year samples of this water be collected by the institution authorities or by a representative of this Department and that these samples be sent to the Division of Laboratories and Research for examination.

In a report dated May 17, 1921, the following recommendations were made:

1. That the small connection between the fire system and the service system upon which a pressure gauge is installed be removed.
2. That no connection be permitted to exist at any time between the two systems.
3. That samples of the water supply of the institution be collected at least 4 times each year and forwarded to the Division of Laboratories and Research for examination.

NEW YORK INTERURBAN WATER COMPANY

A reinspection of the public water supply furnished by the New York Interurban Water Company to the city of Mt. Vernon, and to the village of Mamaroneck, town of Harrison, and the districts of Orienta and Rye Neck, Westchester county, N. Y., was made by Mr. Alfred Mullikin, a representative of this Department on October 4, 1921. Previous inspections of this supply have been made by this Division in 1909, 1915 and 1920 and the reports thereon published in the Annual Reports of the Department for those years.

Mt. Vernon, a city with a present population estimated at 43,000 is located north and adjacent to New York City on the Bronx river. The village of Mamaroneck and the other districts served lie to the northeast of the city and have an estimated population of 9,000. Of the total population, all are served with water from the public water supply. The waterworks are owned and operated by the New York Interurban Water Company under the direction of Mr. H. E. Walbert, superintendent. The water supply of the New York Interurban Water Company is obtained from three sources namely, the Hutchinson river, Tom Paine brook and the Mamaroneck river. The supply from the Hutchinson river consists mainly of the overflow from the New Rochelle reservoirs together with the drainage from the watershed between these reservoirs and the reservoir of the Interurban Company at Pelham. The water from Tom Paine brook is collected in a large reservoir, known as the Mahlstead reservoir, from which it is siphoned to the Pelham reservoir. The water from these 2 sources is then filtered through open slow sand filters. The supply from the Mamaroneck river is collected in a small storage reservoir and then pumped through pressure mechanical filters after coagulation and sedimentation in a preliminary settling basin and after treatment with hypochlorite of lime. The description of these two filter plants will be found on pages 419 and 429, Vol. 2 of the 30th Annual Report of this Department.

After filtration and sterilization, the water passes into a distributing system. The water mains over the entire system are flushed once a year. The average daily water consumption for the month of September was 3,694,554 gallons, of which some 2,377,400 gallons was supplied by the Mamaroneck plant and 1,317,250 gallons by the Pelham plant. Storage is provided by a steel stand pipe.

The Mamaroneck reservoir formed by a timber and stone dam is located about 8 miles east of the center of the city of Mt. Vernon and about 1 mile north of the village of Mamaroneck. Signs are posted to prevent trespassing but the reservoir is not fenced. Monthly inspections are made and copper sulphate is added 3 or 4 times a year to inhibit the growth of algæ. Above the reservoir the drainage area of the Mamaroneck river is about 12.8 square miles. The soil is rocky and traversed by a number of highways along which are numerous houses on the watershed. The river receives surface wash from this populated area. It is also said that the supply is subject to direct pollution from time to time from the overflow of sewers carrying sewage from the city of White Plains. The Pelham reservoir is located about 1½ miles east of the center of the city of Mt. Vernon and north of the New York, New Haven and Hartford Railroad. Although signs against trespassing are posted, the reservoir is not fenced. The physical condition of the water was somewhat impaired at the time of the inspection due to the presence of algæ growths in the reservoir. Located near the inlet pipe leading from the reservoir to the slow sand filters, a barrel is placed and used in connection with the application of copper sulphate for treatment of the raw water at a rate of 5 pounds per day or approximately 0.46 parts per million. The Pelham reservoir is fed by water from the Hutchinson river and the Tom Paine brook. The Hutchinson river has a drainage area of about 2 square miles and receives the overflow from the New Rochelle reservoirs. There are also numerous houses and highways on this watershed which in all probability give rise to pollution of the supply. It was learned that the Hutchinson river receives direct pollution from leaks occurring in a tile sewer laid in Hutchinson boulevard. Tom Paine brook has a drainage area of about 1.9 square miles. The water is collected in two small riprapped ponds in the city of New Rochelle and flows to Mahlstead storage reservoir. The watershed receives less pollution than the other sources. It contains some swamp area above the upper pond and is open to the public. Above the upper pond crossing the brook in Wykagyl park, the city of New Rochelle has recently laid sewers constructed of 24-inch cast-iron pipe with leaded joints. The Mahlstead reservoir is rectangular in shape and riprapped. Although signs are posted prohibiting trespassing, 5 people were fishing from the banks of the reservoir at the time of the inspection. Although the reservoir is treated with copper suphate several times a year, the water contained considerable algæ. Rules and regulations for the sanitary protection of the public water supply of the city of Mt. Vernon were enacted by this Department in 1907.

The Pelham filter plant is located at the Pelham reservoir, 1 mile east of the city of Mt. Vernon and consists of 3 slow sand filters. With a consumption of 1.3 million gallons of water per day, the filters were operating at a rate of 1.16 million gallons per acre per day. The filters are cleaned about every 6 weeks, when ½-inch of sand is removed at each cleaning. Two of the filters were being cleaned at the time of the inspection. The filtered water is sterlized with liquid chlorine which is applied by a Wallace and Tiernan manual control solution feed chlorinator having a pulsometer capacity of 45 c.c. At the time of the inspection chlorine was being applied at the rate of 0.8 parts per million. An additional new chlorine apparatus has been installed, having a pulsometer capacity of 39 c.c. This apparatus is held in reserve.

The Mamaroneck filter plant is located about 1 mile north of the village of Mamaroneck and some 200 feet below the impounding Mamaroneck reservoir. The water from this reservoir flows by gravity to a coagulating basin. It is cleaned every three months. From the coagulating basin the water flows through 4 horizontal pressure mechanical filters. With a consumption of 2.38 million gallons of water, the rate of filtration based on a cross-sectional area of 160 square feet each, would be 162 million gallons per acre per day. Every day two of the four filters are washed giving a 48 hour run between washing for each filter. The first filtrate is not wasted. At the time of the inspection some 200 pounds of alum were being applied to the raw water per day, the rate of application is 0.59 grains per gallon which gave a satisfactory floc to the raw water.

The filtered water is sterilized with liquid chlorine at nearly 1.3 parts per million. From the recent inspection it appears that our previous recommendations have been carried out with the exception that the chlorine cylinder connections have not been arranged so that two cylinders may be kept connected to the apparatus at all times.

The results of the analyses of the filtered and chlorinated water made by the Division of Laboratories and Research and collected at the Pelham plant show nearly 100 per cent removal of turbidity, 50 per cent removal of color, 70 per cent and 53 per cent removal of organic matter as measured by the albuminoid ammonia and oxygen consumed tests respectively. The results of the bacteriological examination show a total bacterial increase of some 92 per cent as indicated by the 20 degree count which is probably due to the fact that one of the filters had just been cleaned prior to the time of the inspection. The results of the analyses of the filtered and chlorinated water collected at the Mamaroneck plant show nearly 100 per cent removal of turbidity, 58 per cent and 47 per cent removal of organic matter as measured by the albuminoid ammonia and oxygen consumed tests respectively. The results of the bacteriological examination show a total bacterial removal of 94 per cent as indicated by the 20 degree count and a removal of 100 per cent of organisms of the B. coli type in all inoculations examined.

In a report upon an inspection of the supply dated December 20, 1921, the following recommendations were made:

1. That as previously recommended the Interurban Water Company maintain at all times a careful supervision over the watersheds tributary to the supply.

2. That adequate pumping machinery be installed at the Westchester avenue sewage pumping station and care be taken to see that no sewers overflow or other sources of pollution continue.

3. That frequent tests of the treated water at both filter plants for excess chlorine be made by the starch iodide method in accordance with the enclosed directions, and the rate of application of the chlorine regulated in accordance with the results of these tests.

4. That the water company make careful daily tests of the raw and filtered water with a view to determining the exact quantity of alum and chlorine required at all times and the rate of application of these chemicals be regulated in accordance with the results of these tests and applied continuously.

5. That copper sulphate be properly applied to the Pelham and Mahlstead reservoirs throughout the year under the supervision of a competent expert in order to prevent the occurrence of algae growths in the reservoir.

6. That the present depth of sand on the Pelham filters be increased by the addition of a suitable quality of sand and at no time should the depth be less than 30 inches.

7. That the water company increase the filter capacity of the Mamaroneck filter plant in order that the rate of filtration will not at any time exceed 125,000,000 gallons per acre per day.

8. That the pressure gauges on the filters of the Mamaroneck plant be tested and the filters washed frequently in order that at no time may the loss of head exceed 10 feet, or a difference of 4 pounds on the gauges.

9. That in accordance with the previous report two chlorine cyclinders be attached to the chlorine apparatus at all times so that an interval of time will not elapse when gas is not applied to the filtered water when changing cylinders.

NIAGARA FALLS (Western New York Water Company)

An inspection of Niagara Falls public water supply was made by Mr. Earl Devendorf on June 6, 1921. Niagara Falls is a city of some 60,000 inhabitants located at the site of Niagara Falls on the Niagara river, and is a large manufacturing center. There are two public water supplies in the city. One, the municipal supply, owned by and operated under the direction of the city authorities, supplies approximately 80 per cent of the domestic population, and the other, owned and operated by the Western New York Water Company, supplies nearly all the large industrial plants in addition to about 20 per cent of the domestic consumption. The investigation of the former supply is covered in a separate memorandum.

The supply is derived from an intake canal of the Niagara Falls Power Company and the purification and pumping plants are located in the southern part of the city on the banks of the canal adjacent to the intake. The water is pumped after preliminary sterilization by liquid chlorine, from the intake well by a low lift centrifugal pump into the coagulating basin and flows by gravity through 14 mechanical gravity filters into a clear water well from which the water is pumped after secondary sterilization with liquid chlorine, by pressure pumps into the distribution system. The average daily consumption for 1920 was 9,788,000 gallons with a maximum of 10,431,677 gallons and a minimum of 7,974,614 gallons per 24 hours.

The conditions surrounding the supply were approximately the same as described in the former report and the detailed description of the purification plant and pumping station will not be given. The monthly average rate of application of sulphate of alumina for 1920 varied from .48 to 1.51 grains per gallon, depending upon the turbidity of the raw water. The monthly average rate of application of liquid chlorine for the year 1920 varied from 2.44 to 4.51 pounds per million gallons. In general approximately two-thirds of the amount of liquid chlorine used is applied before filtration and one-third after filtration. The results of the bacteriological examination of the filtered water before final chlorination show a 97.3 per cent reduction of the 37 degree bacterial count and a 91.7 per cent reduction in the presence of organisms of the B. Coli type. The results of the analysis of the sample of the filtered and treated water collected from a tap at the pumping station and from a tap at the railroad station show a removal of 100 per cent of turbidity and 40 per cent and 28 per cent removal of the organic matter as measured by the albuminoid ammonia and oxygen consumed, respectively. The bacterial reduction as measured by the 37 degree count was 99.9 per cent. There was a removal of 100 per cent of the organisms of the B. Coli type.

In a report on an inspection of the supply dated December 31, 1921, the following conclusions were made:

1. That the public water supply of Niagara Falls as supplied by the Western New York Water Company, was of a satisfactory sanitary quality at the time of the inspection.

2. That the Western New York Water Company have maintained careful supervision including daily laboratory control, of the purification plant to insure a water of safe sanitary quality to the consumers.

It was recommended:

That the Western New York Water Company continue their careful daily laboratory control of the operation of the purification plant in order that a water of safe sanitary quality may at all times be furnished to the consumers.

NIAGARA FALLS (Municipal Supply)

The municipal water supply is obtained from the Niagara river at a point about 2 miles north of the main portion of the city, through an intake extending some 2,200 feet from shore. There is also an emergency intake located some 300 feet from the shore which, however, has never as yet been used. The water is conducted by gravity; the pump well is located on the bank of the river from which it is forced by low lift pumps to the coagulating basin at the filter plant. The water flows by gravity through mechanical gravity filters to the clear water well located under the pumping station from which it is pumped by means of high-pressure pumps directly into the distribution system. The maximum daily consumption for 1920 was 15,520,000, while the average consumption amounts to approximately 10,000,000 gallons per day, the consumption having been cut down since the last inspection, due to the discovery and elimination of leaks.

At the time of the inspection it was learned that the plant is in practically the same condition as described in the former report and the methods of operation are also substantially the same. A detailed description, therefore, of the purification plant will not be again given. The average rates of filtration vary from 8 to 16 million gallons per 24 hours. The filter run is about 24 hours. The amount of alum applied in 1920 varied from .41 to 2.5 grains per gallon, depending upon the amount of turbidity in the raw water which varied from a maximum of 600 to a minimum of 3 and an average of 25. The amount of wash water varied from a minimum of 1.47 per cent to a maximum of 3.22 per cent and an average of 2.38 per cent of the water filtered. The rate of application of hypochlorite of lime varied from a maximum of 8.5 to 2.8, with an average of 4.25 pounds per million gallons. The results of the analyses of the treated water made by the Division of Laboratories and Research and collected from a tap on the public supply show a removal of 100 per cent of the turbidity, 31.7 per cent and 53.1 per cent of the organic matter, as measured by the albuminoid ammonia and oxygen consumed, respectively. The percentage of removal of bacteria of the B. coli type was 100 per cent.

In a report on an inspection of the municipal supply, dated December 31, 1921, the following conclusions were made:

> 1. That the public water supply of Niagara Falls, as supplied by the municipal plant, was of a satisfactory sanitary quality at the time of the inspection.
> 2. That the city authorities have maintained careful supervision, including daily laboratory control of the operation of the purification plant to insure a water of safe sanitary quality to the consumers.
> 3. That the daily water consumption has been cut down considerably, due to the discovery and elimination of leaks.

It was recommended:

> 1. That the city authorities continue their careful supervision, and laboratory control of the operation of the purification plant in order to insure a water of safe sanitary quality being delivered to the consumers at all times.
> 2. That the city authorities continue their endeavors to cut down the water consumption by the elimination of leaks and a house to house survey to discover and remedy service leaks.

NORTH CREEK

An investigation of the public water supply of the village of North Creek, Warren county, was made by Mr. Earl Devendorf, a representative of this Department, on May 31, 1921. A previous investigation of this supply was made in 1917 and a report thereon may be found in the annual report for that year.

North Creek is an unincorporated village, located in the northern part of Warren county on the Hudson river, some 58 miles northwest of Saratoga Springs. There is no public sewer system in the village although some 25 per cent of the houses are served by private sewers which discharge into the Hudson river. The remainder of the village is served by means of cesspools and privies. The population is approximately 500, of which approximately 50 per cent are served with the public water supply. The public water supply is owned and operated by the North Creek Water Works Company, of which Mrs. Gertrude Baker is owner and Mr. Thomas Alexander, superintendent. The main supply is derived from a small upland stream on which a reservoir has been constructed some 1½ miles northwest of the village. An auxiliary source of supply is a pond located in the southern part of the village. An auxiliary supply is obtained from a pond some 100 feet in diameter, having an average depth of approximately 4 feet. This pond is located in the southern part of the village along the main highway. The surface watershed tributary to the pond consists of practically only an acre of land. There are two houses located on the north and south sides of the pond, respectively. The privy at the south side of the pond has been moved to a point opposite the lower extremity of the pond so as to prevent the pollution of the pond supply. The pond supply is derived from a spring located on the south side of the pond, and when used in the past the pond supply has been depleted, indicating that the flow of the spring is not sufficient to supply the needs of the village.

Another source of supply has been derived in the past from a stream located about 1¼ miles southwest of the village. This supply was developed by the laying of some 6,000 feet of pipe from the brook to the village distributing system. The pipe was laid on the surface of the ground and was used during the summertime only. It was stated that this supply had failed during the summer of 1916. This supply, however, has not been used for the past three or four years and at present the pipe line has been disconnected. As another auxiliary source of supply an intake was located in the Hudson river at a point near the upper end of the village and the water pumped by means of a steam pump, operated by steam derived from a locomotive placed at this point by the railroad company. At the time of the inspection the pumping equipment had been removed and the authorities stated that no water had been pumped from this source for the past three or four years.

The watershed tributary to the main supply is about 1½ square miles in area and consists of wholly uninhabited woodland. The land above the reservoir is used as a pasture. There are no permanent sources of pollution upon this watershed. The watershed of the auxiliary brook supply southwest of the village is approximately 2 square miles in area and consists entirely of wooded land. A mountain road is located parallel with the brook and is used for carrying supplies to a fire warden's station located on top of the mountain. There are no permanent sources of pollution on this watershed. The Hudson river above the village of North Creek has a watershed of many square miles, on which are located several hamlets and a large summer population from visitors and campers. It is subject to both direct and indirect pollution from visitors as well as the inhabitants on the watershed and cannot, therefore, be considered as a safe source of supply without adequate purification. As a result of this inspection it appears that conditions remain about the same as at the time of the former inspection except that the Hudson river and the brook southwest of the village have not been used for the past four years.

In a report on an inspection of the supply dated August 22, 1921, the following recommendations were made:

1. That the North Creek Water Company, as previously pointed out, take steps to properly protect the sanitary quality of the main source of supply by making frequent inspections of the watershed in order to discover and eliminate any possible source of pollution.
2. That the spring pond supply should be discontinued as an auxiliary source of supply unless steps are taken to prevent the possible pollution by the construction of adequate drainage ditches to divert surface wash, by the construction of a fence and the proper placarding of the area around the pond to prevent the inhabitants and passers-by from coming in the vicinity of the pond.
3. That the Hudson river be abandoned as an auxiliary source of supply without adequate purification.
4. That if the brook located southwest of the village be retained as an auxiliary source of supply, the waterworks company should make frequent inspections of the watershed to discover and eliminate any possible source of pollution.
5. That if the above sources of supply be insufficient to furnish the required amount of water or if the plans outlined prove impracticable, the waterworks company should take steps to develop a new supply from other sources which should be free from all possible sources of pollution.

NORTHPORT

A reinspection of the public water supply of the village of Northport, Suffolk county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on June 22, 1920. A previous inspection of this supply was made by this Division in the year 1916, and report thereon published in the Annual Report of the Department for that year.

Northport is located in the town of Huntington on the Wading River branch of the Long Island Railroad about 42 miles from New York City. The population in winter amounts to about 2,500 and in summer to about 3,500. Of the total population all are served with water from the public water supply. The waterworks are owned and operated by the Northport Waterworks Company, of which Mr. E. L. Phillipps, 50 Church street, New York City, is president. The water supply is derived from 4 driven wells located about ¾ of a mile south of the village, 2 miles northwest of the railway depot and some 200 feet from the south shore of Northport harbor. From the wells water is delivered by pumping into a circular concrete storage reservoir located near the south edge of the village about ¾ of a mile northeast of the plant. This reservoir supplies the low level district. From this reservoir water is pumped into air pressure tanks located nearby which supply the upper part of the village. The storage reservoir is uncovered. The average daily water consumption in winter is approximately 190,000 gallons or 76 gallons per capita, and in summer approximately 250,000 gallons or 71½ gallons per capita. Since the last previous inspection changes to the supply have been made in the following particulars: A new pump house has been constructed in the vicinity of the wells at a somewhat lower elevation than the old steam plant and is some 200 feet west of the old plant, which is located alongside and east of a spring fed pond. The pipe which formerly connected this pond to the water supply has been completely disconnected. Near this pumping plant 2 new wells have been driven.

The two new wells are 6 inches in diameter and 43 feet deep. These wells are provided with concrete boxes about 5 feet square. They are not flowing wells. The suction mains are directly connected to the newly constructed pumping machinery. The 2 old wells are flowing wells. They are located just south of the old steam pumping plant on the east edge of the pond. Opportunity for pollution of the ground water was noticed only in the vicinity of the new wells. About 100 feet southwest of the new wells is an open vault privy 3 feet deep. This privy is cleaned yearly. It is used by the pump attendant who lives in a house about 75 feet south of the new pumping plant. There are no other houses nearby. In the vicinity of the 2 old wells and spring fed pond, no direct sources of pollution were noticed. The pond and old wells are surrounded by a fence to prevent trespassing. The new wells are not. The pumps are alternately operated 10 hours a day. The plant was installed in 1919, and is maintained in very good condition. About ¾ of a mile north of these plants and alongside of the concrete reservoir is the high level pumping unit. The public water supply is cross-connected with the auxiliary fire supply of the Northport Waterworks Company at the electric power station located at Woodbine avenue near Scudder avenue. The well is located near the boiler room of the electric plant which is in a thickly populated district. There appears to be no direct sources of pollution. If necessary the supply can be turned into the village system.

In a report on an inspection of the supply dated January 18, 1921, the following recommendations were made:

1. That the authorities in charge of the water supply remove the source of pollution within the vicinity of the wells by providing a watertight removal container for the privy and properly removing and disposing of the contents of this container at a remote point in a satisfactory manner.
2. That the area in the vicinity of the new wells be fenced off to prevent trespassing.
3. That the company continue to analyze the water at frequent intervals to detect the presence of any active contamination which may occur at any time and should such contamination be found present at any time, steps be immediately taken to discover and remove the sources of pollution if possible or to properly sterilize the water supply.

NORTHVILLE

An investigation of the public water supply of the village of Northville, Fulton county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 24, 1921. Previous investigations of this supply were made in 1916 and 1918 and the reports thereon may be found in the Annual Reports of the Department for the respective years.

Northville is an incorporated village located in the northern part of Fulton county, some 17 miles north of Gloversville, on the Sacandaga river. There is no public system of sewers and the inhabitants in the village are mainly served by privies and cesspools. The permanent population amounts to some 1,200 inhabitants, of which practically all are served with the public water supply. During the summer the population is increased to some 1,500 by summer visitors. The water supply is owned by the village and is operated under a board of trustees, of which Mr. Scott Partridge is president. The supply is derived from an impounding reservoir on Steenburg creek, located about 2 miles northeast of the village.

The reservoir has a surface area of approximately 5 acres. The reservoir is formed by the construction of an earthen dam having a masonry core wall. The dam has been provided with 2 waste weirs. From the intake the water flows to the village. The land surrounding the reservoir is owned by the village and enclosed with a fence. The watershed of Steenburg creek above the reservoir has an area of approximately 3½ square miles, which is uncultivated. The area is sparsely inhabited, there being 3 houses on it having a total population of approximately 10 people. The houses are, for the most part, located at considerable distance from the stream. At the Horton place, about ½ mile above the reservoir, it was found that no one was living on the farm. It was learned that the farm house is used as a camp. The privy has been moved to a point directly in the rear as was recommended in a former report. As a result of the recent inspection it was found that the conditions on the watershed have changed to some extent. One house on the watershed has been abandoned entirely and another was burned. At the time of the inspection it was learned that a pipe line is laid underneath the highway bridge crossing the Sacandaga river to the Sacandaga Park side of the river. This pipe line is used in time of emergency to supply Sacandaga park with water from the Northville public water supply or to supply Northville with the Sacandaga public water supply.

In a report on an inspection of the supply dated June 21, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply continue to carefully supervise the sanitary conditions on the watershed in order that any insanitary conditions may be discovered and eliminated.
2. That, should the Horton place be again occupied, the privy be moved to the western side of the house, as previously recommended.
3. That, if any difficulty is experienced in carrying out the above recommendations, the village authorities should apply to this Department for the enactment of rules and regulations for the sanitary protection of the public water supply.

NORWICH

A reinspection of the public water supply of the city of Norwich, Chenango county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 9, 1920, accompanied by Mr. C. F. Ames, superintendent of the water company. A previous inspection of this supply was made by this Division in 1908 and the report thereon published in the annual report of the Department for that year.

Norwich is located on the Chenango river in the northwestern part of the town of Norwich, 53 miles southwest of Utica. The present population is 8,300 of whom all are served by the public supply. The waterworks are owned and operated by the Norwich Water Works Company of which Mr. Robert E. Eaton is president. The water supply is derived from Ransford creek, the 2 tributaries of which rise about 4 miles northeast of the city and which have been impounded in two reservoirs located about 2 miles northeast of the city. In times of low flow, water is drawn from Chenango lake located

5½ miles northwest of the city. As an emergency supply water is pumped from the Chenango river. The water from the above sources is chlorinated and filtered through 6 horizontal mechanical pressure filters, installed by the New York Continental Jewel Filtration Company. The water after filtration flows by gravity through a distributing system consisting of 20 miles of cast-iron pipe. The average daily water consumption is 2,000,000 gallons. The city has a sewerage system, the sewage being discharged without treatment into the Chenango river.

Ransford creek, above the point at which the water is impounded, has a drainage area of approximately 3¼ square miles. The watershed is hilly with a gravel and hardpan subsoil and is devoted to farming and pasturing. About 15 per cent of the shed is forested. There are 20 houses on the area served by privies having metal containers which are removed and their contents disposed of at regular intervals by the Water Company. A detailed inspection of the watershed is made twice each year. At the lower end of the creek an open canal has been constructed to by-pass the drainage of 5 farms to a point in Ransford creek below the intake. Chenango lake, the area of which is 0.19 square miles, has a drainage area of 0.86 square miles. The lake is a summer resort and has 1 hotel and 15 cottages. It is used as a source of supply without treatment by these summer residents. The method of disposal of the sewage at the hotel and cottages is chemical closets which have been installed and are maintained by the water company. The intake is located at the northwestern end of the lake where there are no dwellings. From the lake there extends 400 feet of 16-inch pipe to a tunnel through which the water runs for 1,000 feet. Beyond this tunnel the water flows through 1½ miles of pipe discharging into a deep gorge. The water continues flowing in this open stream to the reservoir. This stream is the westerly of the 2 tributaries of Ransford creek from which water is taken in times of high flow. The water company now owns the rights to the entire lake. Ice is cut from the lake each year to supply the cottages in summer, some ice being cut by nearby farmers. Each spring 45 pounds of copper sulphate are applied to each reservoir. Last August the lower reservoir was drained and thoroughly cleaned.

As the city grows it is contemplated developing Gilmore brook as a source of supply. The drainage area of this stream above the proposed intake is 6 square miles.

The filtration plant is located near the east side of the Chenango river. The filters are washed by reverse flow at 5 A. M. each day. With a daily consumption of 2,000,000 gallons per day and using 6 filters the rate of flow is 90,000,000 gallons per acre per day. The coagulant used is aluminum sulphate at a rate of 0.44 grains per gallon. For sterilization, chloride of lime is added, the amount varying from 11 to 26 pounds per day, or with a consumption of 2,000,000 gallons per day this would mean a rate of application of chlorine of from 0.23 to 0.53 p.p.m. The results of the analysis of the filtered water made by the Division of Laboratories and Research, show a total bacterial removal of 99.5 per cent. The absence of B. coli in all of the inoculations show that the filtered water was free from active contamination at the time the inspection was made.

In a report on an inspection of the supply dated March 4, 1921, the following conclusions were made:

1. That the water supply was of a fairly satisfactory sanitary quality at the time of the inspection.
2. That the authorities in charge of the water supply are exercising careful supervision over the watershed.
3. That the filters are apparently being operated in an effective manner.

It was, therefore, recommended: That the authorities continue their careful supervision over the sanitary condition of the watershed and the operation of the purification plant.

OAKFIELD

A reinspection of the public water supply of the village of Oakfield, Genesee county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on March 18, 1921. A previous inspection of the supply was made by this Division in the year 1917, and a report thereon published in the Annual Report of this Department for that year. Oakfield is located about 6 miles north of Batavia. The present population is estimated at 1,500. Of the total population 50 per cent are served with water from the public supply, the remaining population obtaining water from private wells. The waterworks are owned and operated by the municipality under the direction of a board of trustees, of which Mr. C. H. Griffin is president. The water supply is derived from Seymour spring located about ¼ of a mile west of the village railroad station, situated 300 feet south of Drake street and about 400 feet east of the corporate limits of the village. From the spring the water is delivered by pumping through a distributing system consisting of 4 miles of pipe. A steel tank is located in the northwestern part of the village, supported on a steel tower. The average daily water consumption based on a consumption of 80 gallons per capita amounts to 60,000 gallons. This amount is considerably increased during the summer when canning factories draw heavily on the village supply. In general, the details of the waterworks system remain as described in the previous report. The spring is covered over by a small collecting reservoir. The walls of this spring are of concrete and rest on a limestone foundation from which the water is obtained. The roof of the collecting reservoir is also the floor of the pumping station. It is water tight and was in a satisfactory condition at the time of the inspection. An overflow pipe extends from the west wall to a nearby creek. This pipe was placed too near the floor level, and until an additional opening was made in the wall below the pipe, water from the spring flowed upon the pump room floor. The new overflow opening has been roughly cut in the concrete wall and a continual flow of water discharges below the overflow pipe into the creek. A privy owned by the village is located about 150 feet west of the plant at a lower elevation. This privy is very rarely used by the pump attendant but is occasionally visited by trespassers. It is not maintained in a sanitary condition. To the south wall of the pump room is attached a Wallace-Tiernan solution feed manual control apparatus. At the time of the inspection chlorine was not being applied to the water on account of a stoppage in the rubber tubing which leads from the solution jar to the suction main. The chlorine apparatus, aside from the stoppage in the tubing, is in very good condition. From the recent inspection it appears that the previous recommendations have not been carried out, with the exception that extra chlorine has been obtained.

In a report on an inspection of the supply dated April 18, 1921, the following recommendations were made:

1. That the opening in the west wall of the collecting basin be closed, and a properly designed overflow constructed if necessary to care for the surplus water.
2. That the chlorine apparatus be repaired and that chlorine be applied to the water continuously at such a rate as may be found necessary to properly sterilize it, but never at a rate of less than 0.2 r.p.m.
3. That the test for excess chlorine in the treated water be made daily in accordance with the instructions issued by this Department to determine the proper amount of chlorine to apply to the water, and that scales be provided for weighing the chlorine cylinders to check the rate of application of chlorine.

OLD FORGE

A reinspection of the public water supply of the village of Old Forge with special reference to the installation of the department chlorination apparatus was made by Mr. Earl Devendorf, a representative of this Department, on August 25 and 26, 1921. Previous inspections of this supply have been made by this Division in 1918 and 1919, the reports on which may be found in the Annual Reports of the Department for the respective years.

Old Forge is an incorporated village located in the town of Webb in the central part of Herkimer county. The resident population of the village is approximately 750, which is increased however during the summer months to some 3,000. The water supply is owned by the village and operated under the direction of a board of trustees, of which Mr. Walter Marks is president. The water supply is obtained from springs and spring brooks on a mountain side some two miles northwest of the village. The water is collected in two impounding reservoirs formed by the construction of dams across natural depressions, which have capacities of 160,000 and 175,000 gallons. The water flows from these reservoirs to the village distributing system by gravity, crossing the north branch of the Moose river. The daily water consumption is unknown but varies greatly with the season of the year and is said to be steadily increasing, due to the addition of summer homes.

The recent inspection was made as a result of word received in the Department about the middle of August that the regular public water supply of the village of Old Forge had been depleted, due to the long continued drought and to the heavy demands from the large summer population, and that it would be necessary to augment the regular supply by pumping water from the north branch of the Moose river. The president of the village and the health officer were immediately advised that this Department did not consider the water of the Moose river safe for human consumption without treatment, as the rivér drains an extensive watershed on which there are numerous summer resorts. Although the river flows for a long distance above the intake through a wooded and unpopulated region, there is the attendant danger of pollution of this supply of an accidental, incidental or willful nature by fishermen and trespassers. It was accordingly arranged to have a representative of this Department install the Department emergency chlorination apparatus to sterilize the water from the river before being pumped into the mains. This apparatus was installed on August 26 and the operator instructed in the use of the apparatus and the making of the starch iodide determination for excess chlorine in the treated water, by which method the rate of application of chlorine was regulated. The emergency pumping station was located on the north branch of the Moose river at a point where the main from the reservoir crosses the river and some 2 miles in the woods and away from any highway. It was therefore necessary to carry the apparatus to the pumping station where it was installed and the chlorine applied to the water through the suction line of the pump. As estimated from the speed of the pump, chlorine was being applied at the rate of approximately .53 parts per million.

In our previous reports it has been recommended that the village authorities take all the necessary precautions to maintain the supply in a safe and sanitary condition at all times, erecting suitable fences around the springs and reservoirs and posting the area to prohibit trespassing and keeping the reservoir, springs and channels as free as possible from decayed vegetable matter. It was further recommended that the village authorities secure an additional source of water supply of satisfactory sanitary quality as soon as possible. From the recent inspection it appears that the village authorities have endeavored to maintain the supply in a satisfactory sanitary manner although the physical quality of the supply is affected by the high color and turbidity, resulting from the large amount of timber and decayed vegetation in the lower reservoir.

Since the last previous inspection the village authorities have purchased the necessary land and at the time of the inspection were engaged in the construction of a covered concrete reservoir on the top of a hill near the village. At the base of the hill the village authorities were engaged in developing a well supply and had partly dug a basin and were waiting to obtain a well driller. This work was being developed under the direction of Mr. Weller, village engineer. It is understood that plans have not been submitted to the Water Power Commission for approval, as required by law. From a study of the local geological conditions, as observed at the time of the inspection and from a study of the United States topographical sheet for this section, it would appear very unlikely that any sufficient supply of water could be obtained from a well in this locality. The information obtained by our representative at a later date, when he visited the village to obtain the department chlorination apparatus, would appear to verify this statement as it was said that the village, after drilling to a considerable extent and encountering only rock, had abandoned the attempt to develop a well at this point. Before any further attempt is made by the village to develop an auxiliary supply, plans should first be submitted to and receive the approval of the Water Power Commission, as required by law.

In a report upon the supply dated December 31, 1921, the following recommendations were made:

1. That the village authorities endeavor to maintain the present supply in a safe and sanitary condition at all times.
2. That the village authorities at the earliest possible time and before proceeding any further, submit the proposed plans, for augmenting their present supply, to the Water Power Commission for approval in accordance with provisions of chapter 499 of the Laws of 1921.
3. That in case it again be necessary to pump from the north branch of the Moose river, the village authorities should notify this Department immediately and make suitable arrangements for sterilizing the supply by means of liquid chlorine.
4. That the village authorities clean the reservoirs, springs and channels of timber and decayed vegetation in order to improve the physical quality of the water, as well as erect fences and post signs to prevent trespassing in the vicinity and prevent any possible pollution of the reservoir.

OLEAN

A reinspection of the public water supply of the city of Olean, Cattaraugus county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on April 18, 1921. Previous reinspections of this supply were made by this Division in the years 1909, 1912, 1915, 1917 and 1919, and reports thereon published in the annual report of the Department for those years. The present population of the city is estimated at 20,000, of which 90 per cent or more is served with water from the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners, of which Mr. J. B. Gage is president and Wm. Sheehan, superintendent. Mr. Frank Sherburne is in charge of the filter plant.

The water supply is derived from two sources: The first source is old wells located in the southern part of the village; the second, Olean creek, located in the northern part of the village. The water from the wells is used without treatment, but the supply from Olean creek is filtered and chlorinated before entering the distribution system. Two reservoirs are located on a hill in the southern part of the village. The average daily water consumption is approximately 2½ million gallons or 139 gallons per capita, of which one million gallons were being derived from the well supply. There are 15 driven wells located at the foot of South Union street on the northern bank of the Allegany river. The depth to the water in the wells, it is claimed, when the pumps are not operating is 5 feet from the ground surface and 19 feet when the pumps are operating. Each well is provided with a concrete box and cover. The wells are cross-connected to each other by pipe which intersects two suction lines which cross the bed of the river entering a large dug well known as the Cook well. From this well the water flows to the pumping machinery. An automatic chlorine feed apparatus was installed in 1920 but was not connected for use at the time of the inspection.

The new supply is derived from Olean creek in the northern part of the city, a short distance below the Erie railway bridge. From the intake the raw water is pumped to a sedimentation basin from whence it flows into mixing chambers, then to coagulation basins, and then through gravity mechanical filters, after which it is chlorinated and enters the clear water reservoirs. From the clear water reservoir the water is pumped into the city distribution system. Olean creek, above the intake, has a watershed area of about 170 square miles. Most of this area is devoted to agriculture, with the exception of two villages — Franklinville, of over 2,000 population, and Cuba, of over 1,600 population, located 15 or more miles upstream. Franklinville has a sewerage system and disposal plant and disposes of its sewage by broad irrigation. Cuba has no comprehensive sewerage system. Rules and regulations were enacted by this Department January 29, 1919, to protect the supply from pollution to within a distance of 10 miles above the intake. Yearly inspections are made by the city authorities to see that the provisions of these rules are properly carried out.

The new filtration plant was fully described in our report dated November 11, 1919.

Chlorine is applied to the filtered water through a Wallace & Tiernan automatic solution-fed chlorinator at a rate of 0.25 parts per million. The amount of chlorine on hand was two cylinders. Scales are provided for checking the weight of the chlorine. A duplicate apparatus has been provided but is not assembled. A fully equipped laboratory is located in the southwestern part of the building. Tests for turbidity, color, alkalinity, bacterial counts on litmus lactose agar and presumptive tests for B. coli are made daily in the laboratory; tests for excess chlorine by the ortho-tolidin method are also made. From the recent inspection it appears that previous recommendations have been carried out, with the exception that the well supply is not continually chlorinated.

The water supply is cross-connected to and used by the Erie railroad, Pennsylvania railroad and the Vacuum Oil Co., and also used by the P. S. & N. railroad and a private consumer, who distributes the water to a number of private houses. The Erie railroad has a dug well 10 feet in diameter and 30 feet deep, located in the northern part of the village, north of their railroad tracks, a short distance east of the Pennsylvania railroad crossing. This well is constructed with heavy masonry and provided with a loose wooden plank cover. It is not well protected from surface wash, being located on the side slope near the highway. This supply is cross-connected to the village supply, but the village water is only used when the gas engine is unable to pump from the Erie well. The connection is made at a nearby water tank and no check valve is provided. It is alleged that this well is not used for drinking purposes and that drinking water for the railway coaches is obtained at other villages.

The Buffalo and Allegheny Division of the Pennsylvania railroad has a 6-inch driven well located in their yard in the western part of the village. Water is pumped from a 400 foot depth. The P. S. & N. railroad is not provided with separate wells but obtains its water from the village water supply. The Vacuum Oil Company has three separate connections with the village supply, all of which, it is claimed, are provided with double check valves. It is not likely that water from the auxiliary connections would reach the city supply on account of the high city water pressure, but it is possible that under some conditions this might occur.

In a report on an inspection of the supply dated May 20, 1921, the following recommendations were made:

1. That in cases where auxiliary supplies not under the jurisdiction of the city are cross-connected to the city supply, the city authorities

install double check valves to prevent possibility of contamination of the city supply.

2. That the city well supply be properly chlorinated at all times in order to guard against possible pollution.

3. That the city authorities continue their careful and efficient operation of the filter plant.

ONEIDA

An investigation of the public water supply of the city of Oneida, was made by Mr. Earl Devendorf, assistant engineer of this Department, on December 3, 1920. A previous investigation of the public water supply was made in 1911 and a report thereon may be found in the Annual Report of the State Department of Health for the year 1912.

The city of Oneida has a population of approximately 10,000 inhabitants and is located on Oneida creek in the northern part of Madison county, 20 miles west of Utica.

The water supply is owned by the city and operated under a board of water commissioners, of which Mr. William M. Baker is president. The water supply is derived by gravity from a small stream, on which two impounding reservoirs are located some 2 miles south of the city. Approximately 65 per cent of the residents are furnished with the public water supply. The consumption is estimated to vary from 400,000 to 1,000,000 gallons per 24 hours, corresponding to a daily per capita rate of 40 gallons to 100 gallons. The industrial consumption is unknown. The largest industrial user is the Burt Olney Canning Company, whose factory is operated only from June to November. The watershed has an area of 2 square miles which consists mostly of pasture and wooded land having steep hillsides. There are some 16 farmhouses located on the watershed, which, together with the highway traversing the watershed on either side of the valley, constitute the chief sources of contamination. There is apparently no direct discharge of household waste into the stream. The supply is, however, subject to contamination from the fertilized fields and pasture land bordering the stream as well as the accidental, incidental or wilful contamination from visitors or trespassers upon the watershed. Some trouble has been experienced from algae growths in the reservoir. This is said to have been eliminated by the use of copper sulphate.

At the time of the recent inspection it was ascertained that there are apparently no opportunities for direct contamination existing on the watershed. No treatment plant for softening or purifying the supply, as previously recommended, has been built. The authorities in charge of the public water supply were considering the possibility of procuring a new supply by the construction of a reservoir and intake works upon Florence creek, some 22 miles north of the city of Oneida. The proposed site of the reservoir is said to be in the vicinity of the reservoir developed by the city of Rome on Fish creek and is separated only by a hill dividing the two watersheds. It is understood that the Sherrill-Kenwood water district would combine with the city of Oneida and help defray the expense of developing this new supply. There is a cross-connection at the Dodge Pulley Works between an auxiliary supply used for fire purposes and the public water mains. The cross-connection consists of double check and gate valves constructed in a pit and is apparently satisfactorily protected. The auxiliary supply is said to consist of a well. The National Casket Company wells, 125 feet in depth and 6 inches in diameter, have been drilled and are provided with casings extending to the bottom of the wells. At each factory cross-connections exist which consist of a single check and gate valves connecting the auxiliary supply with the public water mains. During the past year the well at the south factory of the National Casket Company was used as an auxiliary source of supply for 6 weeks, during a period of shortage in the source of the main public water supply. This well is located in the city and the ground water sources from which the water is derived are subject to pollution from the thickly populated section. The only protection which this ground water has against pollution from these numerous sources is the natural purification afforded by passage through the soil. The results of the analyses of the sample recently collected from this well indicate that such purification was not being obtained and that water from this well was of an unsatisfactory sanitary quality.

In a report on an inspection of the supply dated January 26, 1921, the following conclusions were made:

1. That the public water supply of the city of Oneida is very hard and is subject to contamination from a sparsely populated watershed and from pasture land as well as from accidental, incidental or wilful contamination from trespassers on the watershed.
2. That there are several cross-connections existing between the city water main and private well supplies which are unsatisfactory in that they are provided with single check and gate valves.
3. That during the period of recent drought the well at the south factory of the National Casket Company factory was pumped directly into the city mains to augment the main public water supply and this water apparently is not of a satisfactory sanitary quality.
4. That the city of Oneida, together with the Sherill-Kenwood water district, is considering the matter of acquiring a new source of public water supply from Florence creek.

It was therefore, recommended:

1. That, providing the present supply is retained, the authorities in charge of the public water supply of Oneida, in accordance with the recommendations formerly made by this Department, make careful and regular inspections of the watershed in order to discover any sources of pollution, and if such sources are discovered, take immediate steps to eliminate them and, furthermore, consider the installation of a softening and mechanical filter plant and that pending the installation of such a plant a chlorination plant for the sterilization of the public water supply be immediately installed and put in operation.
2. That the present cross-connections between the city mains and any auxiliary supplies be removed or provided with double check and gate valves, in accordance with the plans approved by this Department, a blue print of which is attached to this report.
3. That, due to the unsatisfactory location and unsatisfactory sanitary quality as indicated by the recent analysis, no water from the well at the south factory of the National Casket Company factory be pumped into the public mains without adequate sterilization with liquid chlorine.
4. That the authorities in charge of the public water supply secure the service of a competent engineer to make a thorough study of the feasibility of carrying out the proposed plan of securing a supply from Florence creek.

ONEONTA

A reinspection of the public water supply of the city of Oneonta, Otsego county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on February 25, 1921. A previous inspection of this supply was made by this Division in the year 1909 and the report published in the annual report of the Department for that year.

Oneonta is located 82 miles southwest of the city of Albany. The present population is estimated at 11,000, all of whom are served with water from the public supply, in addition to 1,000 people outside of the city limits. The waterworks are owned and operated by the Oneonta Water Company, under the direction of Mr. George I. Wilbur, president. The water supply is derived from 2 impounding reservoirs, the upper one of which is 4¾ miles north of the center of the city, and the lower 3 miles north of the center of the city. There are 2 main pipe lines which deliver the water by gravity to pressure filters located in the northern part of the city, from whence it is delivered through the distributing system. The average daily water consumption is 2,000,000 gallons or 167 gallons per capita. Since the last previous inspection a few changes have been made in the system. The pumping building has been enlarged by making extensions on the east side. A new room was constructed in 1914 for chemical purposes. In the same year the use of alum pots was discontinued and a solution feed system installed. A coal bin and storage room was built in 1920. The authorities are overhauling the filter plant and have already replaced the old laterals and strainers in 4 of the filters with new ones. It is intended to overhaul 1 filter unit each year.

The upper reservoir covers an area of about 75 acres. The reservoir has been treated to prevent the growth of algæ. Fishing in the reservoir is not allowed. Ice is cut during the cold season. Signs are posted near the reservoir to call attention to trespassers that polluting the water is prohibited. There is no fence surrounding the reservoir to prevent trespassing. Inspections of the watershed area and reservoir are made monthly. Some 800 or 900 acres of land above the reservoir are controlled by the water company. There are 24 occupied and about 10 empty houses on the shed. The company has adopted the policy of purchasing all farms possible. The farms now under their control are not inhabited. The privies on the farms are mostly provided with concrete vaults and receive proper care. The lower reservoir covers an area of from 20 to 25 acres. This reservoir is cleaned when found necessary. Its source of supply is springs and brooks. No fishing is allowed nor are horses permitted on the ice during the winter ice cutting. Both reservoirs are located in a well-developed farming district traversed by numerous highways and are subject to considerable pollution from surface wash.

The filter plant is located at the northern edge of the city and is used also as a residence for the plant operator. There are 6 horizontal New York Continental-Jewel filters connected in parallel. They are washed daily. Alum is applied by pumping at a rate of .5 to 1 grain per gallon and at the time averaged .6 grains per gallon. The hypochlorite of lime is applied at the rate of 6 pounds per million gallons or .25 part of available chlorine per million parts of water. The water is used on the D. & H. R. R. for drinking purposes and for boiler use. The supply is cross-connected with the railroad supply which is pumped from the Susquehanna river. One connecting main has a single check valve in the pipe line, which was installed before instructions on valves from this Department were received.

In a report on inspection of the public water supply, dated April 1, 1921, the following recommendations were made:

1. That the company continue its careful supervision over the watershed to detect and eliminate as far as possible all sources of pollution.
2. That the authorities in charge of the water supply sever all connections between their system and the system of the railroad company or provide such connections with double check valves in accordance with the general plan approved by this Department.

OTEGO

A reinspection of the public water supply of the village of Otego was made on December 14, 1920, by Mr. A. I. Howd, assistant engineer in this Department, a previous inspection of this supply having been made by the Department in 1914. Otego is an incorporated village, located in the southwestern part of Otsego county, about 8 miles southwest of Oneonta. The village is also located on the Susquehanna river and Otsdawa creek. The water supply is owned by the village and is under the direction of a board of water commissioners, of which Mr. A. D. Annable is president. The water supply is derived from springs and Otsdawa creek about 2 miles north of the village. Practically all of the population of the villag estimated to be about 500, is served with water from the public wate supply. There are about 4 miles of mains. There is no way of accuratel estimating the domestic water consumption.

The springs, one of the sources of the public water supply, are locate at the foot of a precipitous bank near the west branch of Otsdawa cree and consist simply of small shallow basins which are connected by pip lines to the reservoir. The springs are provided with wooden covers whic are old and in poor condition. The west branch of Otsdawa creek, th other source of water supply, has a watershed area of about 6.7 squar miles above the intake. There are about 40 houses on the watershe The reservoir is constructed of concrete and has a gabled roof over i The water from the creek flows into the upper section of the reservoir an the spring water flows into the lower section. The pipe line to the villag originates in the lower section of the reservoir and the spring water i therefore, ordinarily used. An automatic float, located in this part of th reservoir, opens a valve when the water reaches a certain low level an allows the creek water from the upper section to flow into the lower sectio and unite with the spring water.

The inspection of a portion of the watershed was made after a heav rain. Otsdawa creek was swollen considerably above its normal size an was very turbid and highly colored from the red soil on the shed. Th runoff from the highway, which traverses the watershed, flowed in stream down the steep slopes of the shed into the creek.

In a report on an inspection of the supply, dated February 9, 1921, th following conclusions have been made:

> 1. That the previous recommendations made by this Department fo the improvement of the public water supply of the village of Otego hav not been carried out.
> 2. That the springs, one of the sources of supply, are subject to surface wash and are not properly protected.
> 3. That the west branch of Otsdawa creek (the other source of supply) receives the drainage from pastures, barnyards and manured field and is subject to serious contamination by drainage from privies an by inhabitants of the watershed.
> 4. That the results of analyses of the public water supply indicat that the water is of unsatisfactory sanitary quality and not fit fo domestic consumption.
> 5. That the typhoid fever case rate for the village of Otego is considerably higher than the case rate for the State.

It was recommended:

> 1. That the village authorities take immediate action to secure a adequate water supply of safe sanitary quality and employ a competent sanitary engineer to advise them in this matter.
> 2. That if the springs are to be retained as a source of supply they be properly protected by drainage ditches and provided with concrete curbs and tight padlocked covers.
> 3. That if the west branch of Otsdawa creek is to be retained as a source of water supply, all sources of possible pollution on the watershed be removed and the water subjected to purification before it is delivered into the mains.

PALMYRA

A reinspection of the public water supply of the village of Palmyra, together with a number of proposed auxiliary sources of supply, was made by Mr. Earl Devendorf, representative of this Division, on September 14 and 15, 1921. Previous inspections of this supply have been made by this Division in 1909, 1910, 1913, 1915 and 1919, and the reports thereon published in the Annual Reports of the Department for the respective years.

Palmyra is an incorporated village having a present population estimated at 2,500 and is located in the southwestern part of Wayne county, about 25 miles east of Rochester. Of the total population practically two-thirds are served with the public water supply. The waterworks are owned and operated by the village under the direction of a board of trustees, of which Mr. H. E. Williams is president. The main source of water supply is obtained from a dug well in the southwestern part of the village, known as the Upper Station well, and an auxiliary supply is available from another dug well about 1½ miles east of the village, known as the Lower Station well. The water consumption is estimated at about 80,000 gallons per day. The water is pumped from the well to an iron standpipe 20 feet in diameter and 50 feet in height, located on a hill above the upper well and has a capacity of approximately 118,000 gallons. From the standpipe the water flows by gravity throughout the village. In general the details of the waterworks system remain as described in the previous report.

The recent inspection was made at the request of the village officials, desiring aid in the sterilization of an auxiliary supply being pumped from the well at the Garlock packing plant in the village, as the village supply had become depleted due to the continued excessive drought. From the recent inspection it appears that the previous recommendations of this Department have not been acted upon and that the conditions surrounding the supply were approximately as described in the former reports. At the time of the inspection the small stream passing in the vicinity of the lower well was dry and the ground water tributary to the well supply was not therefore at the time of the inspection subject to any opportunity for pollution from this source. With the return of normal flow in the stream, however, this freedom from pollution from the infiltration of the polluted creek water will not continue and the supply should not be used under any circumstances unless it is first effectively sterilized by means of liquid chlorine.

The village authorities resorted to the use of the Garlock well on September 7, 1921, and were on the average pumping by means of a fire engine for three hours a day. At the time of the inspection the pump was not in operation, as the tractor used in operating the pump had been changed and the tractor in use was not of sufficient horse power to operate the pump. The use of the Garlock well was continued until approximately October 8th. Up to the time of the inspection the authorities in charge of the public water supply had been in the practice of dissolving six ounces of hypochlorite of lime in the well and allowing it to stand until the following day, when the pump would be started again. It was pointed out, however, by the engineer at the time of the inspection that this method of sterilization was very inefficient and probably had little effect, as the sterilized supply remaining in the well from the night before would probably be removed in a very short time by the pump which was delivering water through two fire streams to a nearby hydrant. While the capacity of the pump is not known it probably has a minimum capacity of at least 150 gallons per minute which for three hours of operation would give a minmum average daily discharge of some 25,000 gallons. At the time of the inspection the engineer supervised the erection of a barrel over the well in which a hypochlorite of lime solution was to be prepared and allowed to flow through a rubber garden hose into the well at a point near the pump section. Directions and materials were left for testing for an excess of chlorine by means of starch iodide and for varying the amount of hypochlorite of lime in accordance with the results of the tests. The village officials later advised the Department that they had used ½ pound of chloride of lime to 30,000 gallons of water, giving an estimated rate of application of hypochlorite of lime of 0.66 parts per million. The need for the sterilization of the well was apparent from the result of the inspection as the well is located in the vicinity of a thickly populated community and the ground water surface tributary to the well is receiving pollution from sewer leakage as well as from surface wash in the area in the vicinity of the well, as there is no curbing or cover provided for the well and the ground around the well is not graded nor drainage ditches provided to divert surface wash from the vicinity of the well. The use of such a source of water supply by the village subject to such a crude and inefficient method of purification is attended with grave danger and the village authorities should develop at the earliest possible moment an auxiliary source of water supply which shall be both adequate in quantity and of a safe sanitary quality in order that it may not be again necessary to resort to the use of this well.

At the time of the inspection the Beltey spring, a proposed source of water supply, was investigated. This spring is located about 1½ miles east of the village, at the foot of a ravine between two hills used as pasture land. The flow from the spring was very roughly estimated at 15,000 gallons per day. As there had been no rains in the immediate past and the people residing in the vicinity stated that the flow of the spring never failed, it is probable that this flow represents the minimum available flow from the spring. A small spring pond is impounded at one side of the ravine in which, at the time of the inspection, a large number of geese and ducks were swimming about. A sample of water, however, was collected from the spring above the pond. The springs have not been developed nor protected in any manner and the area about the springs was open to cattle in the pasture. It was stated at the time of the inspection that the spring is not located at sufficient elevation to enable the water to be used by gravity but would necessitate pumping. Before the springs could be used as a source of public water supply it would be necessary for the village to purchase or control the area around and above the spring and protect the spring by the construction of drainage ditches and embankments to divert surface wash and enclose a sufficient area around the spring with a tight fence to exclude cattle and other animals from coming in the vicinity of the spring and causing any possible pollution.

Another source of supply investigated at the time of the inspection was the McNutt springs which are located about two miles south of the village. This supply consists of the flow from the low area and from several springs which have been tiled and piped to the milk house located some 300 feet below the main highway above which the house and barns of the farm are located. At the time of the inspection approximately 1 inch of water was flowing over a concrete weir 1 foot wide giving an estimated flow at the time of the inspection of 27,300 gallons per day. It would be necessary for the village to acquire or control the area above the springs in order that there might be no opportunity for pollution of this supply before it could be used as a source of public water supply. The authorities in charge of the supply stated that from the results of a rough survey made there was a possibility that this supply might be used by gravity. Of the two proposed auxiliary sources of water supply examined, the McNutt spring would appear to be the more desirable. Before any auxiliary supply, however, is developed the village authorities should secure the services of a competent sanitary engineer to investigate and advise them as to the most desirable source or the best and most economical means of developing an auxiliary supply of water.

In a report upon an inspection of the supply dated December 6, 1921, the following recommendations were made:

1. That as previously recommended the village of Palmyra install immediately a liquid chlorine apparatus for sterilizing the water of both the lower and upper wells in order to ensure a water of safe sanitary quality at all times.
2. That the village authorities secure the services of a competent sanitary engineer to make a detailed investigation of the matter of securing a new source of supply and advise the village as to the necessary procedure and best and most economical method of developing an auxiliary source of supply in accordance with the recommendations enclosed in the body of the report above.
3. That the village authorities abandon the use of the badly polluted Garlock well and under no circumstances use this well as a source of public water supply unless some permanent and effective means of sterilizing the water are provided.

PENN YAN

An investigation of the public water supply of Penn Yan was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 9, 1920. A previous investigation of the public water supply was made in 1916 and a report thereon may be found in the Annual Report of the Department for that year.

Penn Yan is a village having a population of approximately 5,000 inhabitants and is located in the central part of Yates county, at the northern end of Keuka lake, 15 miles southwest of Geneva. The village is served by a comprehensive sewerage system which discharges through a sewage disposal plant into the outlet of Keuka lake. The water supply is owned by the village and operated under the supervision of a municipal board, of which Mr. Fred H. Linn is president. The supply is derived by pumping from Keuka lake at a point about 1½ miles southwest of the village. The water is pumped into the distribution system, the excess over consumption going to an open stone masonry distributing reservoir. Approximately 95 per cent of the population is served with the public water supply. The average daily amount of water pumped for the year 1919 as estimated from the pump strokes was 570,748 gallons or 114 gallons per capita. Of the above amount of water pumped there are several large consumers, the most important of which are the New York Central Railroad, the Pennsylvania Railroad, Yates County Canning factory, the Tempter Fruit and Corn Products company and the Garret company. Keuka lake has a watershed, 187 square miles and for the most part is sparsely inhabited. The principal sources of pollution in the immediate vicinity of the intake, are the summer cottages located along the shores of the lake, of which there are a considerable number. The watershed is protected by rules and regulations enacted by this Department and the village employs an inspector during the summer season to control the watershed. While the majority of the privies along the lake are said to be provided with watertight containers, complaint was received from a resident in the village concerning the pollution of the lake in the vicinity of the water supply intake, and the engineer interviewed the residents who stated that during the summer vacation season there were many violations of the water rules leading to the pollution of the water supply in the vicinity of the intake. There are three cross-connections with the city mains. Each connection is of 8-inch pipe and provided with a single gate and check valve located in a manhole and provided with a cast-iron cover.

In a report on an inspection of the supply dated January 20, 1921, the following recommendations were made:

1. That the village authorities provide the most careful continuous supervision of the watershed in order that any insanitary conditions thereon may be discovered and eliminated.
2. That the present cross-connections of the public water mains with auxiliary fire supplies be either entirely separated or provided with double check and gate valves, in accordance with the plans approved by this Department.
3. That, as previously recommended, the village authorities immediately install a chlorination apparatus and treat the water continuously with a proper amount of liquid chlorine in order to guarantee a public water supply of satisfactory sanitary quality at all times.

PERRY

A reinspection of the public water supply of the village of Perry, Wyoming county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department on December 17, 1920. A previous inspection of the supply was made by this Division in the year 1913 and the report thereon published in the Annual Report of the Department for that year.

Perry is located in the eastern part of Wyoming county about 30 miles southwest of the city of Rochester. The present population is estimated at 5,000, practically all of whom are served with water from the public supply. The waterworks are owned and operated by the municipality under the direction of a board of trustees of which Mr. W. S. Sanford is president. The water supply is derived from Silver lake pumped to slow sand filters and then repumped from a clear water well into the distribution system.

Since the previous inspection a slow sand filter, an individual meter valve house, a clear water reservoir and a number of pumps have been added to the waterworks system.

Silver lake, from which the water supply is derived, is approximately 3 miles long and about ½ mile wide. The waters of the lake are subject to considerable pollution from the summer population on its shores. No sewerage system has been constructed to take care of the sewage from the settlements around the lake. The authorities in charge of the water supply make annual inspections of the watershed to detect possible sources of pollution of the lake. Ice is cut from the lake about 200 feet north of the intake of the water supply.

The new filter plant which was constructed in 1917, consists of a slow sand filter of three units, having a total area of about ⅛ of an acre. The filter is provided with a concrete roof. It is operated at an average rate of 1,970,000 gallons per acre per day. Sand is raked every two months and cleaned every two years. The filters were provided with loss of head gauges which were out of operation at the time of the inspection. The clear water reservoir is 80 feet in diameter and 6 feet deep, having a capacity of 300,000 gallons. It is constructed of concrete and covered and provided with manholes and manhole covers.

In a report dated February 5, 1921 on an inspection of the supply the following conclusions were drawn:

1. That the water supply at the time of the inspection was of a relatively satisfactory sanitary quality.
2. That the authorities in charge of the water supply have carried out the previous recommendations of this Department in that the board of trustees have applied for the amendment of rules and regulations for the protection from contamination of the public water supply, although these rules have not been enacted; that the village board of health has engaged a man to keep a strict oversight and report on the sanitary conditions of the watershed as found in the violation of the rules and regulations, and that a purification plant has been properly designed and constructed and is operating in a fairly efficient manner.
3. That, with the present method of sewage disposal, namely, cesspools and privies in the lake district, it is possible that the storm drainage from this district may at times carry considerable pollution into the lake water.

It was therefore recommended:

1. That the authorities continue to maintain careful supervision over the watershed in the vicinity of the lake at all times so that the danger of contamination of the supply may be reduced to a minimum.
2. That the authorities endeavor to increase the efficiency of the filter plant and put in order all of the appurtenances which were not in operation at the time of the inspection.
3. That, if it is found impossible or impracticable to secure a higher degree of purification, the village authorities consider the installation and operation of a chlorination apparatus.
4. That a blow-off valve and waste water pipe be constructed at the clear water well.
5. That the village authorities again attempt to secure the installation of a sewerage system in the lake district in accordance with plans approved by this Department.

PHILADELPHIA

A reinspection of the public water supply of the village of Philadelphia, Jefferson county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on April 14, 1921. A previous inspection of the supply was made by this Division in the year 1918 and the report thereon published on page 283 of the 40th Annual Report of the Department.

Philadelphia is located on the Indian river in the central part of the town of Philadelphia, 17 miles northeast of the city of Watertown. The present population is 850, practically all of whom are served by the public supply. There were also a few farm houses outside of the incorporated village limits that received water from the public supply. The waterworks are owned by the village and are under the control of a board of water commissioners, of which Mr. W. J. Guthrie is president. The water is derived from a spring fed reservoir located 5 miles south of the village from which it flows by gravity through 8 miles of mains. There is no public sewerage system, about three-quarters of the population being served by private sewers which discharge directly into the Indian river, the remaining houses being served by local cesspools and privies. About 8 acres of land around the reservoir are owned by the village, this territory being enclosed by a 5-foot wire mesh fence. The watershed above the springs is level, uninhabited land, and having a sandy subsoil. The reservoir is cleaned once a year, while the watershed is regularly inspected a few times each year.

In a report on an inspection of the supply dated January 29, 1921, it was recommended that the authorities in charge of the supply continue to maintain strict supervision over the area around the basin to prevent trespassing and pasturing and keep the fence in repair and the area in satisfactory sanitary condition.

PHILMONT

A reinspection of the public water supply of the village of Philmont, Columbia county, N. Y., was made by a representative of this Division on October 24, 1921. Previous investigations of this supply have been made by this Division in 1912, 1918 and 1919 and reports thereon published in the Annual Reports of the Department for those years.

The village of Philmont is located about 30 miles southeast of Albany. The population of the village is about 2,200 practically all of which is served with the public water supply. The waterworks are owned by the municipality and operated under the direction of the board of water commissioners. The water supply is derived from Forest lake which is located about 4 miles south of the village at an elevation of some 500 feet above the village. The water supply flows by gravity from the lake to a stone lined distributing reservoir and is thence delivered by gravity to the village. The average daily consumption amounts to approximately 70,000 gallons, about ½ of which is used by the mills in the village. The water supply is protected by rules and regulations enacted by this Department in 1913. There is no comprehensive public sewer system in the village. The recent inspection disclosed that in general the details of the waterworks remain as described in the previous reports with the exception that a rough filter which acts as a strainer has been constructed to treat some swamp water which formerly flowed directly into Forest lake. The officials still allow parties, who have first obtained consent of the board of water commissioners, to fish in the lake. As previously pointed out this practice cannot be given approval by this Department as the opportunity for pollution of the supply is ever present. At the time of the inspection cattle were observed grazing on land adjacent to and sloping toward the lake on the opposite side from the outlet. The village owns a 50-foot strip of land between the lake and the point where the cattle are grazing.

In a report on an investigation of the supply dated November 22, 1921, the following recommendations were made:

1. That the authorities in charge of the public water supply carry out such of the previous recommendations of this Department as have not already been acted upon.
2. That pending the acquisition of land to prevent the use of this land for agricultural and grazing purposes, and the 50 foot strip now owned by the village reforested with evergreen trees.
3. That as previously recommended, if the present practice of allowing fishermen to enter the reservoir is maintained, the authorities should install and operate apparatus for the sterilization of the public water supply with liquid chlorine.
4. That the authorities in charge of the public water supply continue a careful sanitary patrol of the watershed in order to discover and eliminate any sources of contamination that may be found to exist on the shed.

PLATTSBURG

A reinspection of the public water supply of the city of Plattsburg, Clinton county, N. Y., was made by an assistant engineer from this Department on June 14, 1921. Previous inspections of the supply were made by this Department in 1911, 1912, 1914, 1916, 1919, and 1920, reports upon which will be found in the Annual Reports of this Department for the respective years. Rules and regulations for the protection of the supply from contamination were enacted in 1900.

Plattsburgh has a population estimated at 10,909. The waterworks are owned and operated by the city under the direction of a superintendent of public works. Practically all the population is served with the public supply. Water is also furnished to the Hotel Champlain at Bluff Point and to the Plattsburg Barracks where it is reported the water is passed through a filtration plant before being used. The water supply is derived by gravity from one or both of two brooks located on the easterly slopes of the Dannemora mountain about 7 miles west of the village. Storage is provided by the two reservoirs on the West Brook watershed having a combined capacity of 150,000,000 gallons, and increased storage is being provided by the reconstruction of the dam and deepening of the old reservoir at Mead Pond. The water is delivered through two parallel lines of 12-inch pipe which extend from the source of supply to two 1½ million gallon reservoirs near the city. Here they are interconnected but continue on into the city. The average daily water consumption is over 3,200,000 gallons per day or almost 300 gallons per capita. In general the details of the waterworks system remain as described in the previous report, the principal exception being that Scribner pond is reported out of use and the old Mead pond above it is being prepared for use and that liquid chlorine apparatus has been purchased and is in operation.

A heated chlorination building has been provided about 500 feet below the lower of the two reservoirs on the West Brook watershed. This building is equipped with a 12 by 6-inch Venturi meter and a liquid chlorine apparatus adjusted to feed 0.4 of a part per million of liquid chlorine to the water passing through the meter. Four or five spare cylinders of liquid chlorine are provided and an entire duplicate apparatus is on hand with a duplicate set of parts for both apparatus. A portable emergency apparatus has also been procured.

From our recent inspection it apears that the chlorination plant for sterilizing the water taken from West and Mead brooks has been purchased but it is alleged that on account of unsuitable pressure for automatic operation it has been felt necessary by the city authorities to install chlorine apparatus at two points. The apparatus has been installed at only one of these points, namely on West brook which is reported as the only one in use.

Here a chlorination plant has been installed and provided with a suitable meter for measuring the flow and applying chlorine at all times in such proportions as to effectively sterilize the water when properly operated. The old pond on Mead brook is being cleaned and the use of Scribner pond as a reservoir temporarily discontinued. However, the tests of water and reduction in algae and aquatic growths leave much to be desired and there are many flats, particularly in the larger, or upper used reservoir, on the West brook which should be filled in or excavated and the banks steepened.

In a report upon the supply dated July 5, 1921, the following recommendations were made:

1. That metering and chlorination of all the water be continued in such proportions as to properly sterilize it as determined by frequent starch iodide tests and bacteriological examinations.
2. That no use be made of Scribner pond but the work on the old upper pond on Mead brook be completed as soon as possible and the flow from this reservoir be metered and chlorinated.
3. That connections and provision be made at once to treat near the source any emergency or additional supply which may be required from points other than West brook.
4. That the reservoirs be cleared, as far as possible, of aquatic growths.
5. That copper sulphate be used each year prior to the time algae first appears and at such intervals as may be necessary to eliminate such growths.

A supplementary reinspection of the public water supply of the city of Plattsburg, Clinton county, N. Y., was made by Mr. Earl Devendorf, a representative of this Department, on July 28 and August 9, 1921.

An inspection of this supply was previously made on June 14, 1921, and in the report on this inspection under date of July 5, 1921, it was pointed out that no means had been provided for the sterilization of the Mead brook supply. As a result of the unfavorable analyses of samples of water collected at the time of the inspection the surgeon-general of the United States Public Health Service prohibited the use of water from the public water supply of the city of Plattsburg for drinking and culinary purposes on cars used in interstate traffic. The commandant at the Plattsburg barracks furthermore had forbidden the use of the water without treatment for drinking or culinary purposes by the men at the barracks and had requested the city authorities to take steps to improve the water supply.

The recent inspection was made at the request of the city officials of Plattsburg for advice concerning the procedure to be followed in providing a supply of satisfactory sanitary quality. The representative of this Department assisted the city authorities in installing and gave instructions for the operation of the emergency chlorination plant on the Mead brook supply and supervised the sterilization of the distributing reservoir.

At the present time all of the water being used by the city of Plattsburg is being sterilized by means of 2 chlorination plants. An automatic control, venturi operated, Wallace and Tiernan chlorination plant is sterilizing the West brook supply, and a manual control Wallace and Tiernan chlorination plant is being used to sterilize the Mead brook supply.

As a result of the recommendations made at the time of the inspection the city officials have engaged the services of a consulting engineer to advise them on the matter of permanent improvements to the public water supply, involving the construction of additional storage reservoirs, improvements to the present distributing reservoirs and the permanent installation of chlorination plants on the Mead brook as well as the West brook supply.

The results of the analyses of samples of water collected at the time of the last inspection indicate that the sterilization of the supply was being carried on in an effective manner, and that the public water supply was of a satisfactory sanitary quality.

In a report upon the supply, dated September 8, 1921, the following recommendations were made:

1. That the city authorities continue to maintain careful supervision over the operation of the chlorination plants in order that the supply may at all times be effectively sterilized.

2. That the city authorities endeavor to carry out the previous recommendations of this Department as soon as possible, the detailed procedure of which will be given by the consulting engineer employed by the city.

RANDOLPH

An investigation of the public water supply of the village of Randolph Cattaraugus county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on March 31, 1921. Previous investigations of this supply have been made in 1911 and 1915 and reports covering the results of these inspections may be found in the annual reports of the Department for those years.

Randolph is an incorporated village, located in the southwestern part of Cattaraugus county, some 16 miles east of Jamestown. The village has no public sewer system and is served for the most part by privies and cesspools. The population is approximately 1,300, practically all of whom are served by the public water supply. The public water supply is owned by the village and operated under a board of water commissioners, of which Mr. W. L. Rathbone is superintendent. The supply is derived from 2 reservoirs located about 2 miles southwest of the village. The old reservoir impounds the water from the springs and flowing wells, whereas the new reservoir impounds the water from a small stream draining the narrow valley above. The consumption amounts to approximately 300,000 gallons per day. The largest consumers are the Borden Mill factory, which uses approximately 100,000 gallons per day; the Randolph furniture factory which uses about 30,000 gallons per day; and the Electric Light Company's plant which uses some 40,000 gallons per day. The reservoirs are located at the mouth of a narrow ravine which is drained by a small stream. It was stated, however, that there is only one family living upon this watershed and that there are no permanent sources of pollution existing on the watershed. It was furthermore stated that during approximately 75 per cent of the year the stream did not exist above the point where the springs are located. This area is owned by the village and fenced and posted against trespassing. The flow from several springs and wells, located above the reservoirs, is collected and led through a pipe line which extends into the main leading to the village. There is a pipe connecting the two reservoirs and when the flow from the springs and wells is not equal to the demand of the village, water from a reservoir fed by the small stream will enter the spring fed reservoir, since the intake is placed in the spring fed reservoir.

During the past winter the village authorities have dug a new well some 19 feet in depth at a point approximately 25 feet above the old reservoir This well is approximately 12 feet square and the well has not been enclosed with walls. In addition to this dug well 3 2-inch and 1 4-inch drilled wells all 20 feet in depth, have been dug at various locations above and near the old reservoir. These wells were, at the time of the inspection, flowing and discharging into the spring reservoir. In addition to the above improvements the village authorities have engaged the services of an engineer to make a study of the development of an additional source of water supply from a spring flow at a point some 2 miles east of the village of Randolph near the point where the village of East Randolph derives its public water supply. It is proposed in fact to use as a part of the supply the waste water used to run the small Pelton wheel in the East Randolph pumping station. The plan provides for pumping the water to the proposed reservoir, from which it is to be fed to the village distribution system by gravity. The proposed reservoir is to be located at approximately the same elevation as the present reservoir and on a hill some 2½ miles east of the village. The proposed reservoir is to be approximately 200x250 feet in plan and to hold about ½ million gallons.

In a report on an inspection of the supply, dated June 18, 1921, the following recommendations were made:

1. That the village authorities complete the development of the new wells at the earliest possible time in order that it may not be necessary to use the brook water.
2. That in case the new wells do not constitute a sufficient supply, an additional supply be obtained by the development of the proposed plans prepared by the engineer.
3. That in developing the new source of supply precautions be taken in order to prevent possible pollution.
4. That, pending the completion of the above improvements, the new reservoir impounding the surface water be used for emergency only, and after completion of the improvements, the use of the brook supply be discontinued.

RAQUETTE LAKE

A reinspection of the public water supply of Raquette lake was made by Mr. Earl Devendorf, a representative of this Division, on August 26, 1921. A previous inspection of this supply was made by this Division in 1918 and the report thereon published in the Annual Report of the Department for that year.

Raquette lake is an unincorporated summer resort located in the western part of Hamilton county at the southern end of Raquette lake. Sewage in the community is collected in a septic tank, the effluent from which is discharged into the lake below the village. The resident population of the village amounts to some 100 inhabitants. During the summer months, however, this is increased to approximately 300, 75 per cent of which are served with the public water supply. The waterworks are owned and operated by the Raquette Lake Railroad Company, of which Mr. D. Dager is superintendent. The water supply is derived from a spring-fed brook about 1½ miles south of the railroad station and on which a small reservoir has been formed by the construction of an earthen dam. From the reservoir water is delivered by gravity through a distribution system consisting of two miles of mains. In general the details of the waterworks system remain as described in the previous report. The reservoir has been increased in area and depth, due to the work of beavers in raising the dam originally constructed by the railroad company. This has flooded an area covered with timber and vegetation and has a tendency to increase the vegetable organic matter in the water. The watershed draining into the reservoir and brook is small in area and consists of marshy and wooded land in the State forest reserve and is remote from any habitation. As a result of the recent inspection it appears that the railroad company has not extended the intake as recommended in the previous report, and due to the activity of the beavers the area and depth of the reservoir have been increased, flooding a considerable additional amount of vegetation. As a result of this the water appeared to be highly colored.

In a report on an inspection of the supply dated October 17, 1921, the following recommendations were made:

1. That as previously recommended, the railroad company extend the intake or maintain the reservoir free from vegetation in order that the aesthetic quality of the water may be improved.
2. That the railroad company make frequent inspections of the supply in order to prevent any contamination of the public supply.

RENSSELAER

An inspection of the public water supply of Rensselaer was made by Mr. W. J. Erickson of this Division on April 26, 1921. The pumping station was inspected and it was found that conditions remained the same as described in the report on the inspection of 1920. The filter plant was not in operation as the filters were only operated at night. This is due to the fact that a lower rate for power is then obtained. The electrically driven pumps are used and the steam power plant is held in reserve. Daily presumptive tests for B. coli and for excess chlorine are made. Weekly chemical analyses are made by Mr. James Caird, chemist, of Troy.

RICHFIELD SPRINGS

An investigation of the public water supply of the village of Richfield Springs, Otsego county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 12, 1921. Previous investigations of this supply have been made by the Engineering Division in 1908, 1916, 1918 and 1919. The reports thereon may be found in the Annual Reports of the Department for the respective years.

Richfield Springs is an incorporated village located in the northern part of Otsego county, at the northern end of the Canadarago lake. The resident population is approximately 1,600, which is increased to 3,000 during the summer months by visitors. The village is served with a public sewer system which discharges into the lake. The water supply is owned by the village and operated under a board of water commissioners, of which Mr. H. E. Schooley is president. The supply is derived by pumping from Allen lake to two distributing reservoirs located one-half mile east of the village, from which point it is delivered to the distributing system in the village, after passing through two pressure mechanical filters. The consumption is estimated to vary from 60,000 gallons to over 475,000 gallons per 24 hours. The water in the distributing reservoirs was low at the time of the inspection, due to the fact that the operator at the pumping station located at Allen lake was absent on account of illness. The area surrounding the distributing reservoirs is fenced to prevent trespassers or animals from coming in the vicinity of the reservoir, and drainage ditches have been constructed around the easterly and southerly sides of the reservoirs to prevent surface wash from entering the public supply.

The superintendent stated that no alum is being used in connection with the operation of the filters, and the alum tanks which were formerly used have been disconnected. The filters are washed daily with raw water by reversing the flow through the filters. After washing the first filtrate is allowed to waste until it becomes clear. The filters are two Hyatt pressure mechanical filters. The village authorities have, in conjunction with the underwriters' association, endeavored to make available, at times of fire, a sufficient supply by the installation of an electrically operated valve on the main opposite the filter plant which will allow the filters to be by-passed.

In a report on an inspection of the supply dated July 21, 1921, the following conclusions were made:

> 1. That the village officials in charge of the public water supply have carried out in part our former recommendations by eliminating the cutting of ice on the reservoirs, as well as the cutting of grass with horses on the land surrounding the reservoirs.
>
> 2. That the filtration plant is not being properly operated, inasmuch as no alum or other coagulant is applied, and the rate of filtration is at times of maximum consumption in excess of the rate at which such filters are commonly operated to afford satisfactory purification.
>
> 3. That the installation of a by-pass on the line leading from the distributing reservoir to the village distributing system, by which the filter plant is cut out of service at times of fire, constitutes a menace

to the purity of the supply, inasmuch as when used it will allow the entrance of raw unpurified water into the village mains.

4. That the village authorities are at the present time engaged in the construction of a gravity line from Allen lake to the distributing reservoirs.

It was, therefore, recommended:

1. That the village authorities in charge of the public water supply continue as in the past to effectively safeguard the sanitary quality of the water, by making frequent inspections of the watershed of Allen lake in order to discover and eliminate any possible sources of pollution that may be found to exist on the watershed.
2. That the use of the by-pass at the filter plant be discontinued, and that instead the village authorities enlarge the present filter plant, in order to provide sufficient quantity of water during times of maximum consumption and at times of fire.
3. That, pending the remodelling of the filter plant, a chlorination plant be installed and the water sterilized at all times.
4. That, as previously recommended, the village authorities engage a competent sanitary engineer to aid them in carrying out the above recommendations.

RIPLEY

An inspection of Ripley public water supply was made by Mr. Earl Devendorf, a representative of this Division, on June 8, 1921. Ripley is an unincorporated village located in the northwest corner of Chautauqua county, near Lake Erie, some 65 miles southwest of Buffalo. The population is approximately 1,000 inhabitants, all of which are furnished with the public water supply. The water supply is owned and controlled by the Ripley Water Supply Company, of which Mr. F. M. Randall is president. The supply is derived from the north fork of Twenty-Mile creek, at a point about 2 miles southeast of the village, where a dam has been constructed. The supply is stored in reservoirs on both the north and east forks of the streams, from which points it is led by gravity to a covered distributing reservoir. From this distributing reservoir the water flows by gravity to the village.

The conditions surrounding the supply were practically the same as described in the former report, which recommended that the company make every effort to correct any insanitary conditions on the watershed, applying to this Department for the enactment of rules and regulations for the sanitary protection of the shed if any difficulty should be encountered in correcting any insanitary conditions, and that purification of the supply should be provided by filtration or sterilization with liquid chlorine, or possibly both. The recent inspection discloses that the water company has not provided any treatment for the supply. The cover of the distributing reservoir was partially broken and badly in need of repair.

In a memorandum on an inspection of the supply dated December 31, 1921, the following conclusions were made:

1. That the water company have not carried out the former recommendations made by this Department by providing for the filtration or chlorination of the supply.
2. That the roof of the distributing reservoir was in poor repair.

It was recommended:

That the water company continue their careful supervision of the sanitary conditions on the watershed, in order to discover and remove any possible sources of pollution that may be found to exist on the shed, and that they give further consideration to the previous recommendations of this Department for providing filtration or chlorination of the supply, and that they repair the roof of the distributing reservoir.

ROME

A reinspection of the public water supply of the city of Rome was made by Mr. A. I. Howd of this Division on July 19, 1921. Previous inspections of this supply were made by the Department in 1911, 1915 and 1918 and the reports thereon published in the 33rd, 36th and 39th Annual Reports of the Department respectively.

The city of Rome, having a population of about 26,400, is located in the central part of Oneida county about 15 miles northwest of Utica. Of the total population practically all are served with the public water supply. The waterworks are owned and operated by the municipality under the direction of a board of water commissioners of which Mr. Ray Armstrong is superintendent.

The water supply is derived from the east branch of Fish creek about 12 miles northwest of the city. The water from the creek is conducted through a pipe line to a storage and distributing reservoir located about 5½ miles north of the city and a small concrete building containing two chlorinators and a recording apparatus for a Venturi meter is located about ½ mile below the reservoir. The water is delivered to the city by gravity. The daily water consumption ranges from 5.5 to 12 million gallons, the average being about 8 million gallons of which about 3 million gallons are used for commercial purposes. The average daily water consumption for 1920 was 8.5 million gallons or about 320 gallons per capita per day. In general the details of the waterworks system remain as described in the last previous report.

In a report upon a reinspection of the public water supply dated November 19, 1921 the following conclusions were drawn:

1. That the authorities in charge of the water supply have carried out the previous recommendations of this Department in regard to protecting the watershed and in regard to providing duplicate apparatus for the chlorination of the water.
2. That the recommendation in regard to making the starch iodide test for the presence of excess chlorine in the water has not been carried out.
3. That the records at the chlorination building are inconsistent.
4. That the results of the analyses of samples of water collected at the time of the inspection indicate that the water was not being chlorinated effectively.

It was therefore recommended:

1. That the authorities in charge of the water supply take immediate action to carry out the recommendations of this Department in regard to making a daily test for the presence of free chlorine in the chlorinated water supply.
2. That the amount of chlorine applied to the water be increased so that a slight excess of chlorine is maintained in the water at all times.
3. That more satisfactory and accurate records of operation of the chlorination apparatus be kept.

ROSENDALE

A reinspection of the public water supply of Rosendale was made by Mr. W. J. Erickson of this Department, on June 9, 1921. Previous inspections were made of this supply in 1912 and 1915, and are reported upon in the Annual Reports of this Department for the respective years.

Rosendale, which is an incorporated village of about 1,000 inhabitants, is located in the eastern part of Ulster county, 7 miles southwest of Kingston on the Rondout creek. There is no public sewer system in the village, though there are a few private sewers emptying into the Rondout creek The water supply is owned by the village and is under the control of the board of water commissioners, for which Mr. James Brown is superintendent. About 90 per cent of the population use the supply, which is derived from a small spring-fed stream impounded in a reservoir located in the southeastern portion of the village. This reservoir supplies the lower section of the village. A few houses located in the higher sections of the village are supplied from a stream impounded in a reservoir about a mile and a quarter south of the village.

The watershed tributary to the low service reservoir is about 70 acres in area. This area is uninhabited. Signs warning against pollution of the supply are posted. The superintendent makes frequent visits to the watershed in order that any contamination may be prevented. The area of the watershed supplying the high service system is about 0.7 square miles in area. There are but two houses on the watershed. One is owned by the village and is unoccupied. The other is located about a mile above the reservoir. The area on which the buildings are located is practically level. A manure pile is located about 100 feet from the stream, as is also a pigpen and a chicken yard. The privy is well back from the stream. The reservoir is fenced so as to exclude animals and trespassers. The water in the reservoir was clear and little vegetation was noticed.

In a report on an inspection of the supply dated June 29, 1921, the following recommendations were made:

1. That the farm on the watershed of the high service be placed in a sanitary condition so as not to menace the supply.
2. That the local authorities continue their careful supervision and frequently inspect the sanitary conditions on both watersheds.
3. That, in case the village experiences any difficulty in improving the conditions upon the watershed, they apply to this Department for the enactment of rules and regulations for the sanitary protection of the water supply.

SACANDAGA PARK

An investigation of the public water supply of Sacandaga Park, Fulton county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 24, 1921. Previous investigations of this supply were made in 1916 and 1918, and the reports thereon may be found in the Annual Reports of the Department for the respective years.

Sacandaga Park is a popular summer resort located in the northeastern part of Fulton county, on the Sacandaga river, 15 miles north of Gloversville. The park is controlled and operated by the Fonda, Johnstown and Gloversville Railroad Company. The permanent population at the park amounts to about 30 inhabitants. During the summer time, however, the population ranges from 2,500 to 3,000 inhabitants, and on holidays the visitors may increase the population to a total of some 5,000 or 6,000 persons. The water supply is owned and operated by the Fonda, Johnstown and Gloversville railroad, of which Mr. J. S. Plunkett is manager. The supply is derived from reservoirs located in the hills about 3 miles southwest of the park. There are two reservoirs, the upper reservoir having a total area of some 4 acres. The lower reservoir, which has an area of about ½ acre, serves as a distributing reservoir. Water is distributed by gravity throughout the park. The area around the reservoir is inclosed with a fence and posted to prevent visitors, causing any possible pollution of the water supply. The total watershed tributary to the reservoirs is about 1 square mile in area, and is wholly uncultivated. As a result of the recent inspection, it was found that a pipe line is in existence which connects the public water supply distribution system of the village of Northville with the Sacandaga Park distribution system. This pipe line crosses the river and is supported by the highway bridge. The Sacandaga Park supply is used at the railroad station, and is said at times to be used for filling the tanks used for drinking water in the coaches of the Fonda, Johnstown and Gloversville railroad.

In a report on an inspection of the supply dated June 20, 1921, it was recommended:

> That the railroad company continue to exercise careful supervision of the watershed to prevent any pollution of the supply.

SAG HARBOR

A reinspection of the public water supply of the village of Sag Harbor, Suffolk county, N. Y., was made by Mr. Alfred Mullikin, a representative of this Department, on August 9, 1921. Previous inspections of this supply have been made by this Division in 1909, 1914, and 1920, and the reports thereon published in the Annual Reports of the Department for those years.

Sag Harbor has a present population estimated at 3,500, about 20 per cent of which are served with water from the public water supply. The waterworks are owned and operated by the Sag Harbor Water Company, of which Mr. Henry F. Cook is president.

The water supply is derived from Long pond, about 1 mile southwest of the village. From the pond the water flows by gravity in Ligonee creek to a diverting dam, and thence through a 12-inch pipe to collecting wells, from which the water is pumped into the distribution system. The water supply is sterilized with liquid chlorine before being delivered to the consumers. The details of the waterworks system remain as described in the previous report of this Department.

The watershed tributary to the supply is about 0.1 square miles in area and consists of marshy land, having practically no pollution, but is, however, traversed by several highways and a railroad. There are no permanent sources of pollution on the watershed.

No action has been taken by the water company to carry out the previous recommendations of this Department in regard to employing an engineer to advise them as to the measures necessary to assure an adequate supply of satisfactory physical and sanitary quality, nor in regard to using the 4 original wells, with provision for aeration, followed by sedimentation and filtration for the removal of the iron.

In a report dated September 15, 1921, on an inspection of the supply, the following recommendations were made:

1. That the authorities in charge of the water supply maintain constant and careful patrol over the watershed, and see that the pumping plant is properly operated at all times.
2. That daily tests of the treated water for excess chlorine be made by the starch iodide method.
3. That complete daily records be kept of the amount of water pumped and the amount of chlorine used.
4. That the authorities in charge of the water supply carry out the previous recommendations of this Department that have not as yet been acted upon.

SALAMANCA

A reinspection of the public water supply of the city of Salamanca was made by Mr. W. J. Erickson on December 16, 1920. A previous inspection was made in 1916, the report of which may be found published in the 37th Annual Report of the Department.

Salamanca is a city of about 9,000 inhabitants located on both sides of the Alleghany river in the south central part of Cattaraugus county. Practically all of the city is served by the public sewer system which discharges directly into the Alleghany river. The water supply is owned by the city and is under the supervision of the board of water and light commissioners. The supply is derived from two sources, namely: Newton Run and 19 driven wells. The intake on Newton Run is located about 1½ miles north of the village. The water flows from this source to the distribution system by gravity. The wells are located near the north bank of the Alleghany river in the western part of the city. The water from this supply is pumped into the distribution system, consisting of about 22 miles of water mains. Practically all use the public supply and the average daily consumption is about 1,700,000 gallons a day. The waters of Newton Run are collected and impounded in a storage reservoir from which it passes to an intake reservoir and a distributing reservoir. The water is usually allowed to flow over the dam and over the natural bed of the brook to the intake located a short distance below.

The lower or distributing reservoir is located west of the brook 300 feet below the intake. It is possible to feed this reservoir from the upper storage reservoir through a pipe which connects the two. In times of heavy rains when the brook gets very turbulent the pipe connecting the intake with the distributing reservoir is shut off so that only the stored water is used. Should a heavy rainfall come suddenly before the caretaker has been able to close the valve, this turbid water is prevented from entering the mains by starting the pumps at the pumping station at the wells and maintaining a strong back pressure. The watershed tributary to the intake has an area of about 1½ square miles. The section is very hilly and is generally of a shaly structure overlaid with clay and gravel. There are three houses on the shed which are not ordinarily occupied, and there appears to be little chance of pollution.

Six new wells have been driven during the past year and are similar to the 9 original wells. As one of the original wells located about 20 feet from the river has been abandoned on account of the possibility of contamination and tightly capped, 14 wells are now in use. These wells are located at a safe distance from the river, the nearest being about 60 feet from the river's edge and are all tightly capped, and the suction line is tightly sealed to the casing. Each well is provided with concrete boxes so as to prevent pollution from the river water in times of freshets. There are 10 houses within 500 feet of the well and 25 houses within 1,000 feet of it. All these houses have been connected with the public sewers which have been laid in accordance with plans approved by this Department. The section in the vicinity of the well is of cast-iron pipe with leaded joints.

In a report on an inspection of the supply, dated January 17, 1921, it was recommended:

1. That the surface supply be filtered or not delivered to the consumers when rendered turbid by heavy surface runoff.
2. That the well boxes be surrounded with embankments so as to prevent the polluted river water from reaching them in times of flood.
3. That the city install and put in operation apparatus for the sterilization of all water delivered to the consumers by liquid chlorine.

SALAMANCA (Erie R. R.)

An inspection of the water supply used by the Erie railroad in the city of Salamanca was made by Sanitary Inspector W. J. Erickson on December 16, 1920. The water supply is derived from a dug well located south of the blacksmith shop in the shop yard of the Erie railroad from which it is pumped to the tanks and distribution system. No accurate data is available as to the consumption. Sixty to 70 engines are filled daily and all the water used by the shops and yards for industrial purposes is obtained from this well. Besides supplying the potable water for the shops, yard, depot and passenger coaches, water is also shipped from this well to other points on the line. The floor of the platform on which the pumps are set is constructed of planking. It is possible for oil drippings and other waste to get into the well through the open joints in these planks which were oil soaked at the time of the inspection. The well is dug through about 30 feet of gravel in which a narrow strata of clay was encountered, 6 feet of clay and 10 feet of gravel, below which there is clay strata. The conditions surrounding the well appear satisfactory. The nearest sewer to the well is about 175 feet distant and is constructed of cast-iron with leaded joints.

In a report on an inspection of the supply, dated January 21, 1921, it was recommended:

1. That wooden platform be immediately replaced by a properly drained, tight cement floor.
2. That the railroad consider placing the pumps in a separate pit or building not above the well.
3. That the railroad maintain the surroundings in a sanitary condition at all times so as not to endanger the well water.

SARANAC LAKE

A reinspection of the public water supply of the village of Saranac Lake, located in Essex and Franklin counties, N. Y., was made by Mr. Alfred Mullikin, a representative of this Department, on November 5, 1921. Previous inspections of this supply have been made by this Division in 1916 and 1919 and the reports thereon published in the annual report of the Department for those years.

Saranac Lake, a village with a present population estimated at 6,000, is located on the Saranac river, in the Adirondack mountains. Of the total population all are served with water from the public water supply. The waterworks are owned and operated by the municipality under the directions of a board of water commissioners of which Mr. E. E. Bellows is president. The water supply is derived from McKenzie pond located about 2½ miles east of the village in the Adirondack mountains. From the pond the water flows by gravity to the pumping station, where it is pumped into the distributing system, consisting of 25 miles of pipe. The average daily water consumption is approximately 1,400,000 gallons. Storage is provided by an equalizing reservoir about ½ mile southwest of the city. The reservoir is divided into two compartments and is surrounded by a substantial wire fence about 6 feet high. There appeared to be no permanent sources of pollution. Inspections of the reservoir are made once a week. The watershed of McKenzie pond, with the exception of 44 acres owned by the village, is owned by the State and has an area of 2.78 square miles. It is practically all wooded and is situated in a mountainous region. There are no houses on the shed and, therefore, little opportunity for pollution. McKenzie pond has an area of 0.35 square miles. Diverting dams direct water to the pond from several small streams. There is a considerable amount of dead timber along the shores of the pond.

The results of the microscopical examination show the presence of a small number of plants of the Diatomaceae order, known as Asterionella.

In a report on an inspection of the supply, dated December 5, 1921, the following recommendations were made:

1. That the authorities in charge of the water supply continue the careful supervision of the sanitary conditions on the watershed in order to discover and eliminate any possible sources of pollution that may be found to exist.
2. That consideration be given to providing aeration and sedimentation to the water from McKenzie pond and the treatment of the pond with copper sulphate in accordance with the directions outlined in the body of the report above in order that a water of satisfactory physical quality be assured at all times.
3. That the authorities in charge of the public water supply secure the services of a competent sanitary engineer to advise them as to the detailed procedure and the best and most economical methods of carrying out the above recommendations.

SCHENECTADY

A reinspection of the public water supply of the city of Schenectady was made by a representative of this Department on March 17, 1921. The reinspection was made upon the receipt by this Division of information that there was an epidemic of gastroenteric disturbances in the city. Previous investigations of the supply were made by this Department in 1917, 1918 and 1920, and reports thereon transmitted under dates of June 11, 1917, July 24, 1918, and March 31, 1920.

The water supply of the city of Schenectady is obtained from three dug wells at the waterworks pumping station located 2½ miles west of the city on a flat piece of land lying between the south bank of the Mohawk river and the hills which rise abruptly from the plain about 1,000 feet south of the river. The pumping station and the chief engineer's residence, just west of the station, are provided with plumbing fixtures, including flush toilets. The sewage and wastes from these fixtures are disposed of through a cast-iron sewer which passes directly over well No. 1 and discharges into the Mohawk river.

The inspection of 1920 was made on receipt by the Engineering Division of this Department of information that the number of cases of gastroenteric disturbances in the city was greatly increased above the number normally occurring, and that this increase had followed a noticeable turbidity in the water.

As a result of that investigation it was pointed out that the public water supply of the city of Schenectady had received polluted water from the Mohawk river and that it seemed probable that the epidemic of gastroenteric disturbances and the 50 odd cases of typhoid fever which occurred some 3 weeks later were caused at least in part by this contamination, and it was accordingly recommended that the ends of the 2 24-inch suctions in the gallery manhole be suitably sealed, that at least 2 sections of each suction be removed at a point between the gallery manhole and the river and the 4 ends thus exposed sealed with cast-iron flanges and tight gaskets and the excavation refilled with impervious material and that the pipe galleries, unless removed entirely, be thoroughly cleaned. It was also recommended at this time, as had been previously urged, that the sewer carrying the sewage from the toilets in the pumping station and the chief engineer's residence be relocated as far as possible from the wells and laid with cast-iron pipe and leaded joints at a suitable grade and at a reasonable distance from the ground.

The recommendations regarding the sealing and cutting of the 2 24-inch suctions were carried out before March 31, 1920, when the plant was reinspected by a representative from this Department, but no steps had been taken at that time toward the elimination of the sewer crossing well No. 1.

During the first part of March, 1921, it was learned by this Division that there had been an outbreak of gastroenteric disturbances in Schenectady of a similar character to that of March, 1920, but not so severe as the one of that year. Mr. Earl Devendorf, assistant engineer in this Department, was, therefore, on March 17, 1921, sent to Schenectady to inspect the condition of the water supply. An examination of the records of the river elevations indicated that during the first week of March water in the river had been from 10 to 12 feet above normal and that for the 4 days following March 4th it had been above the elevation of the floor of the suction pipe galleries mentioned above. An examination of the suction vacuum records showed that the water in the wells had risen in a corresponding manner.

A study of the results of analyses of samples collected indicates that without question the water supply of the city was contaminated in March, 1920, and March, 1921, and the comparison of the results of the examination of the samples taken at different parts of the system indicates that most of the pollution was apparently from well No. 1. The contamination of this well in March, 1920, was, as pointed out in the previous report, undoubtedly due mainly, if not entirely, to the entrance of river water into the well through the open 24-inch suction, and continued for some time after the direct flow had ceased probably by the ground water carrying into the well polluting matter deposited by the flow in the soil surrounding the well. The source of pollution of the well water in March, 1921, cannot be so definitely determined. It is possible and probable that the rise of the river and the consequent rise of the ground water level may have caused the ground water entering the well to carry into it some of the pollution left in the gallery and the surrounding soil the year before. It is also possible that, owing to the porous nature of the soil, the river water may, at the time when the river level was high, have found its way from the river through the soil into the well, or that changes in the hydraulic condition of the ground water may have caused pollution from some other source to enter the well. Well No. 1 is so arranged with its open joint masonry that it probably receives more water from the upper strata than the other wells. Another possible source of pollution of well No. 1 is the sewer passing over it. Whether the polluting matter reaches the well continuously or only under certain hydraulic conditions, such as may occur after heavy rains or at high stages of the river, is of course not known, since regular examinations of the water have not been made to determine this fact.

It is obvious, however, not only from the results of the analyses and the examination of the conditions surrounding the supply, but also from the fact that epidemics of gastroenteric disturbances and typhoid fever have occurred in the city, and that the water supply is, at least at times, subject to contamination, and for that reason unsafe for domestic use without treatment. It is possible that, by improving the conditions at the wells, water may be obtained that will be safe without treatment during the larger part, or perhaps the entire year, but this can only be determined by careful observations and a series of analyses covering at least one year; and until this is done it would seem necessary, if a safe water is to be delivered to the city, that the entire supply be continuously sterilized with a proper amount of liquid chlorine. It may, of course, be possible, later on, if the results of studies of the kind just mentioned so indicate, to dispense with the chlorination except under certain conditions, or when the river is above a certain level. Even under such conditions, however, the period of chlorination should extend over a sufficient time before and after a period during which conditions are such that the water is probably unsafe to prevent any possibility of contamination reaching the consumers.

In a report upon the supply dated May 12, 1921, it was recommended:

1. That a new sewer, properly laid with cast-iron pipe and lead joints, at a suitable grade and at a reasonable distance below the surface of the ground, be installed to care for the sewage from the pumping station and the engineer's house, and that this sewer be extended along the south side of the pumping station toward the east and then northerly to the river, being kept as far from the wells as possible.

2. That when the new sewer is completed the present sewer be cut between the highway and the river and disinfected, filled with cement grout and sealed in the manner described in the body of this report.

3. That careful studies be made of the water in the wells to determine whether the contamination which has been found at certain times is continuous or intermittent, and if intermittent at what periods it occurs.

4. That these studies include bacteriological examinations of samples from suitable points, made at least three times a week, and more frequently during times of high water and heavy rains, and complete or partial chemical analyses of samples at similar points at frequent intervals.

5. That the authorities in charge of the water supply immediately install apparatus for the sterilization of the supply with liquid chlorine and apply liquid chlorine to the water continuously, and in such quantities as may be found necessary to give a reaction for excess chlorine in the treated water and satisfactorily sterilize the supply, until the

results of the studies previously recommended definitely establish the fact that the water is at certain times safe for human consumption without treatment; and that, should this fact be established, the supply be treated with liquid chlorine continuously during the period in which there is danger of contamination, and extending over sufficient time before and after such period to afford a delivery of a safe water to the consumers at all times.

SENECA FALLS

A reinspection of the public water supply of the village of Seneca Falls, Seneca county, N. Y., was made by Mr. Alfred Mullikin, assistant engineer in this Department, on March 17, 1921. Previous inspections of this supply were made by this Division in the years of 1910, 1915, 1918, and 1920, and reports therein published in the Annual Reports of the Department for those years.

Seneca Falls is located in the town of Seneca Falls, near the north end of Cayuga lake, 42 miles west of Syracuse. The present population is estimated at 7,000. Of the total population, 80 per cent are served with water from the public water supply. The remaining 20 per cent are supplied from private wells. The waterworks are owned and operated by the Seneca Falls Water Company, under the direction of Mr. H. A. Carmer, local manager, and Mr. A. N. French, superintendent. The president, Mr. Herbert Payson, and other officials of the company reside in Portland, Me. The water supply is derived from Cayuga lake. The water is pumped at the lake shore through pressure mechanical filters into a distributing system. A steel standpipe is located in the northern part of the village on State street. The standpipe was cleaned last in 1917. The average daily consumption varies slightly during the year. In February it amounted to 1,000,000 gallons, and in March to 1,250,000 gallons, or 180 and 220 gallons per capita, respectively. In general, the details of the waterworks system remain as described in the previous report. The village supply is connected at several points with private industrial supplies. Cayuga lake forms a part of the New York State Barge Canal system and control gates have been installed at Mud lock on the outlet of the lake, by which its level may be varied to suit the requirements of the canal. The watershed has on it several municipalities including Ithaca, Aurora, Cayuga, Dryden, Freeville, Newfield, Trumansburg and Union Springs. The total population on the watershed is estimated at about 30,000. The city of Ithaca discharges its sewage after preliminary treatment into the lake, and some of the other villages discharge sewage directly into the lake or its tributaries. A large number of cottages along the shore of the lake have house drains and private sewers leading directly into the lake. In addition to this, the lake receives surface drainage from populated districts.

At the north end of the lake the Seneca river, now a part of the New York State Barge Canal, discharges into the lake just above the outlet and the control gates at Mud lock. The character of the watershed is very similar to that of Cayuga lake. The river, however, below the outlet of Seneca lake, receives the sewage of Geneva, Waterloo, and Seneca Falls. The sewage of Geneva is discharged into the river without treatment, as is part of that from Waterloo and Seneca Falls, while the remainder from the two last named places receives only preliminary treatment in settling tanks. This river is polluted with sewage from the population of about 25,000 people, most of which receives no treatment, and none of which receives more than preliminary treatment. In addition to this several industrial establishments, including the Empire mills and the Waterloo Woolen mills, discharge trade waste and domestic sewage into the stream. Normally the flow of water in Cayuga lake is northward and the polluted water of the Seneca river when it reaches the lake mixes with the lake water and flows north through the outlet at Mud lock. When the control gates at Mud lock are closed, or partly closed, so that the flow from Cayuga lake and the Seneca river is greater than the outflow through the gates at Mud lock, the polluted water of the river backs up into the shallow north end of the lake for several miles and considerably beyond the intake of the waterworks.

The water is pumped from the lake through four pressure mechanical filters. Alum is used as a coagulant and is applied from solution tank to the suction main. There is no coagulation basin. About 1,500 pounds were used during the month of February, or equivalent to a rate of 0.36 grains per gallon. A chlorine apparatus was installed and first operated on September 30, 1920. Chlorine has not been used since the latter part of February, 1921. The water is sterilized by the water company at such times as it seems most necessary. No scales are provided for checking the weight of chlorine, nor is there a duplicate apparatus. From the recent inspection it appears that the previous recommendations of this Department have not been carried out.

In a report on an inspection of the supply dated March 30, 1921, the following conclusions were made:

1. That the water company has not as yet taken action along the lines recommended by this Department, and that although the water supply was apparently free from active contamination at the time of the inspection, it is derived from a source subject at all times to pollution and at some times grossly polluted and cannot be considered of entirely satisfactory quality unless effectively purified.
2. That such purification can probably best be carried out by rapid filtration preceded by coagulation and settlement in a coagulation basin of at least two hours' detention and followed by sterilization with liquid chlorine.
3. That there are several connections between the public water supply system and private industrial systems deriving their water from polluted sources which endanger the quality of the village water.

It was, therefore, recommended:

1. That the authorities in charge of the public water supply of Seneca Falls carry out at once our previous recommendations as have not as yet been acted upon, namely:
    - (a) That the water be sterilized by the continuous application of liquid chlorine in such proportions as may be necessary, but at no time at rate of less than 0.2 part per million.
    - (b) That frequent tests of the treated water for excess chlorine be made by the operator at the filter plant, in accordance with the instructions issued by this Department and the rate of application of the chlorine regulated in accordance with the results of these tests.
    - (c) That daily tests be made of the raw water to determine the quantity of coagulant needed and the alum applied in accordance with the results of these tests.
    - (d) That a coagulating basin having a capacity equal to not less than two hours' flow be constructed and used in connection with the operation of the plant.
2. That all connections between the lines of the public water system and private supplies be severed, or if this is not practical such connections be equipped with double check valves arranged in accordance with the general plan approved by this Department.

SHERBURNE

A reinspection of the public water supply of the village of Sherburne, Chenango county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 8, 1920. A previous inspection of the supply was made by this Department in 1914 and a report thereon published in the Annual Report of the Department for that year.

Sherburne is located in the northeastern part of Chenango county, about midway between Utica and Binghamton. The present population is 1,500, of whom all are served by the public water supply and 300 outside the limits of the village are served by the public water supply. The waterworks are owned and operated by the village under the supervision of a board of waterworks, of which Mr. W. W. Benedict is president. The water supply is derived from Mad brook and is impounded in two reservoirs 1½ miles east of the village, from which it flows by gravity to the mains. As an auxiliary supply a well has been dug west of the village from which water may be pumped into the system.

Mad brook above the intake has a drainage area of about 3½ square miles, which is mostly cultivated and contains some pasture and forest land. There is one school building and about ten houses on the watershed, the former being served by chemical closets and the latter by privies. Since the previous inspection two farms from which contamination might reach the supply have been purchased. An inspection of the watershed is made three times each year. The waters of the lower reservoir are treated with copper sulphate every two weeks during the summer to prohibit algae growths. Ice is cut from the reservoir during the winter.

An auxiliary dug well supply was installed in 1918. The well is 31 feet in diameter and 22 feet deep and is provided with a reenforced concrete casing and is covered by a conical slate roof. The well was dug through clayey loam, gravel and blue clay before the stratum of water-bearing gravel was reached. The pumping machinery consists of a Worthington duplex pump having a capacity of 1,000 gallons per minute and operated by a steam engine attached to the pump. The nearest house in the vicinity is some 500 feet west of the well.

In a report dated January 21, 1921, on an inspection of the supply the following conclusions were drawn:

1. That the public water supply of Sherburne is ordinarily of fair sanitary quality but subject at times to small amounts of active contamination, due probably to surface wash from manured fields, pasture land and barnyards.
2. That at certain times of the year growths of algae give rise to objectionable tastes and odors, but these odors are chiefly objectionable from the esthetic standpoint.
3. That the chief points where contamination from human sources might occur are the two farms about ¼ mile above the upper reservoir on the cross road.
4. That the large storage capacity of the reservoir tends to minimize the effect of any pollution which might reach the waters of the brook, but that this storage cannot be relied upon to furnish sufficient purification at times of heavy rains.
5. That there is some danger of contamination of the supply by workmen at times when trees are planted on the land owned by the village.
6. That there is no evidence to connect the water supply with the causation of the cases of typhoid in the village in 1913.

It was therefore recommended:

1. That in case of recurrence of algrae growths in the reservoirs, the village authorities apply copper sulphate to the reservoirs in the proportion of 0.5 parts per million.
2. That every precaution should be taken to prevent surface wash from reaching the brook from the two farms above mentioned.
3. That every care be taken to prevent contamination of the supply by workmen when engaged in planting trees on the watershed near the upper reservoir.
4. That the village authorities request every householder upon the watershed to report at once any case of infectious disease in his family to the health officer so that proper precautions may be taken to prevent any waterborne infection reaching the water supply.

SHORTSVILLE

An investigation of the sanitary condition of the public water supply the village of Shortsville, Ontario county, was made by Mr. Earl Devendor assistant engineer in this Department, on December 17, 1920. A previou inspection of this supply was made in 1915 and a report thereon may b found in the 1915 Annual Report of the State Department of Health.

Shortsville is an incorporated village located in the northern portion Ontario county on the Canandaigua outlet, some 17 miles west of Genev The population at the time of the inspection was approximately 1,300. Th village has no sewer system and is served by means of cesspools, septic tank and privies. The public water supply is owned by the village and operate under a board of water commissioners, of which Mr. F. J. Bullock is president. The supply is derived from 2 drilled wells located about 1 mile sout of the village. Water from these wells is pumped to a standpipe and sto age tank from which the supply is distributed by gravity. The consumptio varies from 42,000 gallons per day to 90,000 gallons per day. Well No. is located some 100 feet south of the pumping station and is 6 inches i diameter and 103 feet in depth. The soil encountered in drilling the wel is said to be loam for the first 3 feet, sand and quicksand for the nex 15 feet and in rock for the balance of the distance. At the time of th inspection some seepage was noticed along the inner walls of the concret pit surrounding the well. Well No. 2 is located some 200 feet southeas of the pumping station and collecting well and at an elevation approximately 15 feet higher than Well No. 1. This well is a 6-inch drilled wel 86 feet in depth. A concrete chamber with a cover is provided around th well. There is some opportunity for pollution of this chamber, inasmuc as the concrete walls have not been carried above the surface of the groun sufficiently to prevent the entrance of surface wash. There is opportunit for surface water that may enter the chamber to flow into the well, fo the casing is not sealed. Water from this well is siphoned into the collecting well. The village owns the property surrounding the wells, pumping station and standpipe and the area is fenced. A farmhouse and bar are located some 1,200 feet east of the village property. The pumps ar used to pump the water from the collecting well to the standpipe and village distributing system. At the pumping station no sanitary convenience are provided for the operator.

In a report on an inspection of the supply, dated February 4, 1921, th following recommendations were made:

1. That, as previously recommended, the casing of Well No. 2 b sealed in order to prevent the opportunity of any surface water enterin the well supply.
2. That, as previously suggested, a privy with a removable containe be provided for the use of the operator at the pumping station.
3. That the authorities in charge of the public water supply continue their careful supervision of the supply in order that a wate of sanitary quality may at all times be furnished the inhabitants of th village.

SIDNEY

A reinspection of the public water supply for the village of Sidney Delaware county, N. Y., made by a representative of this Division on July 18, 1921. The published annual report of the Department for 1904 contains a description of the filter plant and reports on inspections of the supply are to be found in the annual reports for 1908, 1909, 1913 and 1919. No rules for the protection of the watershed have been enacted.

Sidney has a population of about 2,700, nearly all of whom are furnished with the public water supply. The village is located on the Susquehanna river in the northwesterly angle of Delaware county, about 2 miles southwest of Oneonta. The waterworks are owned and operated by the village under the direction of a superintendent. They were taken over from the Sidney Waterworks Company in the latter part of 1919. The water supply is derived by gravity from 2 sources, namely, impounding reservoirs on Collar brook and on Peckham brook. The water consumption has been estimated by the engineer in charge at 600,000 gallons per 24 hours. The watershed tributary to the Collar brook supply embraces about 1⅜ square miles of mountainous land. This watershed contained only 5 houses. The watershed tributary to the Peckham brook supply is approximately 5 square miles of rather sparsely populated country, largely forested, but used for light farming and pasturage. Thirteen houses were observed on this watershed, all but 3 of these houses being remote from the streams. Two open gravity mechanical filters are provided in the dam from which a main extends to the village. The conditions of the Sidney water supply appear to be substantially the same as noted in previous reports with the exception of the change of ownership and the following reported improvements: The house near the Collar brook supply has been bought and burned; lumbering operations on Collar brook stopped; 20,000 trees set to shelter Collar brook reservoirs; limited ice cutting only and under rigid inspection; copper sulphate treatment introduced last year; that an effort to trade land along the stream for upland had been defeated by popular vote, and that improvements in the purification plant had been discussed with a consulting engineer.

In a report on an inspection of the supply, dated August 27, 1921, the following recommendations were made:

1. That the village authorities carry out our previous recommendations of this Department as soon as possible.
2. That the treatment of the reservoir water in the spring with a proper proportion of copper sulphate be continued.
3. That an additional and larger pipe be laid from the village to a new point of discharge from the Peckham reservoir.

SIDNEY CENTER

A reinspection of the public water supply of the village of Sidney Center, Delaware county, N. Y. was made by Mr. N. H. Baier, sanitary inspector in this Department, on March 3, 1921. Previous inspections of the supply were made by this Department in the years 1909 and 1915, and reports thereon published in the Annual Reports of this Department for those years.

Sidney Center is located in the central port of the town of Sidney on Carr creek, a tributary of the Susquehanna river. The present population is 300, 50 per cent of whom are served by the public supply. The waterworks are owned and operated by the Sidney Center waterworks, of which Mr. C. C. Shaw is president. The water is derived from Herrick Hollow creek, a tributary of Carr creek. A reservoir has been constructed at a point about 1¾ miles south of the village. There was no way of estimating the consumption of water in the village. The village has no sewerage system, the houses being served by local cesspools and privies. Herrick Hollow creek, which rises about 3 miles south of the village, has a watershed consisting of some 360 acres of which 50 per cent is cultivated, 25 per cent forested and 25 per cent pastured. There are 5 houses on the shed having a total population of 18 people, and one small stock farm. The construction and location of the privies and barns are such that it is possible for pollution from them to reach the stream. The subsoil is sand, gravel and hardpan underlain by sandstone. The watershed is inspected four times each year.

It was observed at the time of the inspection that a number of small springs were seeping into the reservoir. The water flows for part of the distance over the surface of land which is used for grazing purposes. The reservoir has been thoroughly cleaned, the old intake pipe at the bottom has been replaced by a new one, located about 3 feet from the bottom and better circulation has been provided by the construction of a spillway. The insanitary conditions on the watershed have, however, not been abated, the enactment of rules and regulations has not been requested nor has apparatus for sterilizing the supply been installed.

In a report on an inspection of the supply dated March 29, 1921, the following recommendations were made:

> 1. That the authorities in charge of the public water supply take the necessary steps to remove the sources of pollution on the watershed and, if necessary, apply to this Department for the enactment of rules and regulations.
>
> 2. That consideration be given to the installation of a modern purification system to remove the color and turbidity and to render the water safe from a sanitary standpoint.
>
> 3. That, in the meantime, a chlorinating plant be installed to sterilize the supply and that chlorine be applied to the water in the proper amount and at all times.

SMYRNA

A reinspection of the public water supply of the village of Smyrna, Chenango county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department on December 8, 1920. Previous inspections of the supply were made by this Department in 1911 and 1915 and reports published thereon in the Annual Reports of the Department for those years.

Smyrna is located about 30 miles southwest of Utica and has a population of 270, practically all of whom are served by the public water supply. The waterworks are owned by the village and are under the direction of a water board, of which Mr. F. R. Taylor is president and superintendent.

The main source of water supply is a dug well located near the built-up section of the village. Some water is also obtained from springs located ½ mile northwest of the village. The water from the well is pumped and the water from the springs flows by gravity to the reservoir from which it flows by gravity through the distribution system.

The sanitary conditions surrounding the well are not entirely satisfactory. There are 6 houses within 200 feet of the well which are served by cesspools and it is possible that contamination from this source may reach the water supply. There are no houses on the watershed and around the springs.

The previous recommendations of this supply in regard to providing for the construction of the sewerage system or abandoning the supply and securing a new supply of unquestionable sanitary quality and in regard to installing an apparatus for sterilizing the supply with liquid chlorine pending the carrying out of the above recommendation, have not been carried out.

In a report dated February 4, 1921, on an inspection of the supply the following recommendations were made:

> 1. That the village authorities consider the installation of a modern sewerage system so that the pollution of the present well supply by local cesspools may be eliminated.
>
> 2. That the area about the springs be fenced in order to prevent cattle from straying onto the land and to keep off trespassers and that frequent inspections of the watershed be made.
>
> 3. That chlorinating apparatus be installed and put in operation to sterilize the water supply.
>
> 4. That frequent tests be made of the chlorinated water for excess chlorine in accordance with the directions issued by this Department and the rate of application of the chlorine regulated in accordance with the results of these tests.
>
> 5. That if it is found impractical to improve the conditions surrounding the supply, they develop a new source of supply of unquestionable purity, properly chlorinating the present supply until the new supply is ready for use.

SODUS

A recent inspection of the public water supply of the village of Sodus was made by Mr. Earl Devendorf, assistant engineer in this Department, on December 8, 1920. A previous investigation of this supply was made in 1915 and the report thereon published in the 1916 Annual Report of the State Department of Health.

Sodus is located in the northern part of Wayne county about 30 miles east of Rochester. The water supply is owned by the municipality and operated under a board of trustees, of which Mr. Henry Pett is superintendent. The supply is derived from a well, located about one mile south of the village. The excess over consumption is stored in a reservoir located on a hill near the village. Approximately 80 per cent of the population is served with the public water supply. The consumption varies from 39,000 gallons per 24 hours during the winter to over 110,000 gallons per 24 hours during the summer. As a result of this inspection it was ascertained that the privy at the pumping station had been removed. The manhole on the top of the well has been raised about 2 feet and the cover is kept locked. During the past summer two wells have been drilled about 20 feet east of the old well and about 15 feet apart. The wells, known as No. 1 and No. 2, are 43 and 46 feet in depth, respectively. In both cases loam was first encountered and then quicksand and then limestone rock at about 19 feet below the surface of the ground. The casing in well No. 2 was driven to a depth of 30 feet sealing the well but with well No. 2 it was impossible to drive the casing into the rock and after pumping several days the ground surrounding the casing sank. The wells were tested during the dry spell in the fall of 1920. The surface of the water in the wells was approximately 8 feet below the ground surface at the beginning of the pumping. Within 10 or 15 minutes the water surface would drop to some 18 to 20 feet below the ground elevation and remain constant at that elevation with a rate of pumping of 60 gallons a minute. At the time of the inspection a mixture of waste water and oil from the pumping station was being discharged into a ditch near the pumping station a short distance from the well. When the well surface is lowered, as it is during a drought, a kerosene taste and odor is noticeable in the water and that when dead ends of the distribution system are blown out it is particularly observed. The conditions on the lands surrounding the pumping station and well are practically the same as those described in the 1916 report.

In a report on an inspection of the supply dated January 7, 1921, the following recommendations were made:

(1) That, as previously recommended, the authorities in charge of the public water supply purchase additional land surrounding the wells and provide a suitable fence around the wells.

(2) That a privy with a removable container be provided at the pumping station, as previously recommended.

(3) That the village authorities consider the general information given above with regard to the development of the new wells and if necessary retain a competent sanitary engineer to aid them in working out the details.

(4) That a drain pipe be provided for carrying the waste water and oil away from the vicinity of the well in the general manner described in the body of the report.

ST. JOHNSVILLE

An investigation of the public water supply of the village of St. Johnsville, Montgomery county, N. Y., was made by Mr. Earl Devendorf, assistant engineer in this Department, accompanied by Dr. James S. Walton, sanitary supervisor, on March 7, 1921. Previous investigations of this supply have been made in 1907, 1911, 1912, 1914, 1915 and 1918 and reports thereon may be found in the various Annual Reports of the State Department of Health.

St. Johnsville is an incorporated village located in the northwestern part of Montgomery county, on the Mohawk river, some 7 miles east of Little Falls. The population is approximately 3,000. The village is served by a system of sanitary sewers which discharge into the Mohawk river without treatment. The public water supply is owned by the village and operated under a board of water commissioners, of which Mr. J. A. Rainey is president and Mr. J. H. Schiemer is superintendent. The main supply is derived from springs located near Lasselville, about 6 miles northeast of St. Johnsville. At this point the water is collected into a small reservoir from which it flows by gravity to a cast-iron pipe line to two concrete storage reservoirs located about ½ of a mile north of the village. From these reservoirs the water flows by gravity to the distributing system. The consumption amounts to about 300,000 gallons per 24 hours, of which an average of 30,000 gallons per day are used for commercial purposes. This corresponds to a per capita consumption of 10 gallons per day for industrial use and 90 gallons for domestic use. The supply receives no purification.

At the distributing reservoirs a pipe line is located in the creek bed and provided with gate valves for taking water from Zimmerman creek which flows by the reservoir. In the past, during times of shortage of water, and at the present time when the reservoirs are cleaned, water from Zimmerman creek is allowed to flow into the reservoir. The small reservoir and springs located near Lasselville were not visited at the time of the inspection. It is stated, however, that the condition of the springs and reservoir remain about the same as noted at the time of the former inspection. The reservoir and some of the stone drains leading from the springs were cleaned out last fall. The village now owns the entire watershed around the springs consisting of 40 acres of land, and it is planned to enclose this with a tight wire fence and post the area to prevent trespassing.

In addition to the above source of supply there is a small spring supply located on the Brown property north of the village, which is used by eleven families and in addition serves two drinking fountains and the hydrant from which the sprinkling cart used for sprinkling the village streets is supplied. The masonry walls of the reservoir had not been carried up above the surface of the ground and no ditches provided for diverting the surface wash away from the vicinity of the reservoir. The reservoir is located on the western bank of the small creek and highway running north of the village and near the factory of the Dairyman's League. There are no nearby permanent sources of pollution but the spring is subject to accidental, incidental or wilful contamination from chance visitors to the spring, since the area surrounding the spring is not fenced. The amount of water supplied by the spring flow is not known. It is stated, however. that the supply has proved adequate in the past for the number of consumers using this supply.

The recent inspection was made as a result of complaints received at this office regarding the occurrence of tastes and odors in the village water supply. At the time of the inspection it was found that the odors and tastes in the main supply had been noted on Monroe and Cottage streets and in the small spring supply on North Division street. At the Brown residence on North Division street, however, at the time of the inspection no tastes or odors were observed in the supply and the family stated that no odors or tastes had been noted for the past two or three weeks. In this connection it should be noted that the spring supply had been cleaned out, according to the statement of the superintendent, some three weeks previous. At the Englehart and Conrad residences on Monroe and Cottage streets samples of water were collected for analysis. The water collected from the Englehart residence on Monroe street was observed to have a very slight aromatic taste and odor, which was more noticeable in the water drawn from the hot-water faucet. The family stated that this odor had been noticeable since the fore part of January, 1921. At the Conrad residence on Cottage street no taste or odor was observed in the water drawn from the cold-water faucet, although an aromatic odor could be detected in the hot water in the tea kettle found on the stove at the time of the inspection. No complaints had been received from residents located in other parts of the village and it is thought that the slight odor complained of had been noticed by those residents living near the reservoir and having a more acute sense of taste and smell than the other residents.

The reservoirs were visited at the time of the inspection and samples of growths of aquatic organisms were collected from each reservoir and brought to this office for identification. The organisms collected from the distributing reservoir were found to belong to the chlorophyceae, while the organisms collected from the small spring reservoirs were found to be diatomaceae and mainly symbella. A letter was transmitted to the village authorities advising them to treat the water with copper sulphate in the ratio of 3 pounds per million gallons and to repeat the dosing if found necessary in order to prevent the multiplication of the organisms causing the taste and odors in the water supply.

In a report upon the supply dated March 22, 1921, it was recommended:

1. That the village authorities apply copper sulphate in proper amounts in the distributing reservoir at the first appearance of the aquatic organisms in order to prevent the growth of the organisms and the consequent tastes and odors.
2. That the village authorities absolutely sever the Zimmerman creek supply from the main supply by removing a section of the cast-iron pipe connecting the two supplies.
3. That in case Zimmerman creek water supply is used, the village authorities provide for purification of this supply either by filtration or by sterilization of the supply with liquid chlorine.
4. That, in view of the shortage of the water supply the village authorities continue the installation of meters in order to minimize the waste and make a careful survey of the distribution system to discover and eliminate leaks.
5. That, the reservoir of the small spring supply be covered to prevent the entrance of foreign substances and the growth of aquatic organisms.
6. That the area surrounding the springs be fenced, a curb provided and ditches dug to prevent surface wash entering the spring supply.
7. That the authorities in charge of the public water supply erect a tight fence provided with a locked gate around the watershed of the Lasselville springs and post the area against trespass in order to eliminate the possibility of pollution of the supply by visitors to the watershed.

ROUSES POINT

A reinspection of the public water supply of the village of Rouses Point, Clinton county, N. Y., was made by Mr. W. W. Young, assistant engineer in this Department, on June 12 and 13, 1921. Previous inspections of the supply were made by this Division in 1910, 1911, 1914, 1918 and 1919, and the reports thereon published in the Anuual Reports of this Department for the years 1910, 1911, 1914, 1919 and 1920.

Rouses Point is a railroad center, with a population estimated at 1,700, located on the outlet end of Lake Champlain, 190 miles north of Albany and about 50 miles south of Montreal. Practically the entire population is served by the public water supply. The waterworks are owned and operated by the village under the direction of a board of water commissioners.

The water supply is derived by pumping from Lake Champlain through screened orifices located 1 foot above the bottom of the lake, about 1,200 feet from the shore, where the water is 10 to 15 feet deep. No storage is provided. The present water consumption appears from the pumping records to be about 400,000 gallons per day, 230 gallons per capita per day. A large proportion of this is used by the Delaware and Hudson Railroad Company. In general the details of the waterworks system remain as described in the previous report with the exception of the fact that apparatus for applying liquid chlorine to the water has been substituted for the calcium hypochlorite apparatus.

This new chlorinating apparatus is of the manual control solution feed type and is connected to the suctions of both of the pumps. The apparatus was installed in the early part of July, 1920 and a second cylinder of chlorine was required for installation about the middle of March of this year. No extra cylinders or set of parts are kept on hand.

It was impossible to check the operation of the chlorination plant, for the reason that one of the connections had broken on the 21st of May and had not been repaired at the time of the inspection, June 12 and 13. Assuming that 400,000 gallons a day were pumped for 250 days during which 100 pounds of liquid chlorine were used the rate of application would appear to be about 1 pound of chlorine per million gallons of water, or about 0.12 parts per million, an amount generally found too small to effectively disinfect a water supply.

In the report of this Department made following the inspection of October 9, 1918, recommendations were made that the amount of hypochlorite be increased to such an extent that a sample drawn from the pump discharge would contain a slight excess of free chlorine at all times and that the former recommendations regarding the installation of a modern and permanent filtration plant be carried out. In the last previous report it was recommended that liquid chlorine be substituted for calcium hypochlorite and that consideration be given to the installation of a modern filtration plant

From the recent inspection it appears that these recommendations have been acted upon to the extent of installing apparatus for the treatment of the supply with liquid chlorine but apparently no steps have been taken toward the installation of a modern filtration plant.

In a report upon the supply dated July 7, 1921, the following recommendations were made:

1. That the chlorinating apparatus be immediately repaired and put in operation.
2. That an extra apparatus be secured and kept in readiness for use at all times.
3. That the water be treated with chlorine continuously in such quantities as may be necessary to effectively sterilize it.
4. That the rate of application of the chlorine be determined by tests of the treated water for excess chlorine made at frequent intervals by the attendant in charge of the plant in accordance with the instructions issued by this Department, but that the rate never be less than 0.2 parts per million.
5. That the chlorine cylinder be kept on a platform scale and that the weight of the cylinder and its contents be recorded daily to check the rate of application of the chlorine.
6. That an extra cylinder of chlorine be kept on hand at all times.
7. That the village consider the installation of a modern filtration plant.

A supplementary reinspection of the public water supply of the village of Rouses Point, Clinton county, N. Y., was made by a representative of this Department on August 18, 1921. An inspection of this water supply was previously made on June 13, 1921, and in a report on this inspection under date of July 9, 1921, it was pointed out that the apparatus for treating the water supply with liquid chlorine, broken on May 21, had not been repaired.

The analyses of the water made at the time of this previous inspection showed active contamination and upon the receipt of this report the Surgeon General of the United States Public Health Service prohibited the use of this water for drinking and culinary purposes on railroad cars engaged in interstate traffic. The recent inspection was made at the request of the United States Public Health Service and the Delaware and Hudson Railroad

Company, who advised us that the chlorine apparatus had been repaired and put in operation.

As a result of this inspection it was found that the apparatus had been repaired and was operating in a satisfactory manner. It was also found that necessary spare parts had been ordered.

In a report dated August 23, 1921, it was recommended that the previous recommendations of this Department be fully carried out.

STAMFORD

A reinspection of the public water supply of the incorporated village of Stamford with special reference to the sterilization of an auxiliary source of supply, was made by Mr. Alfred Mullikin and Mr. Earl Devendorf on September 14, 22 and October 1, 1921. Previous investigations of this supply have been made by this Division in 1908, 1917 and 1919, reports on which may be found in the Annual Reports of the Department for the respective years.

Stamford is located in the northeastern part of Delaware county and has a resident population estimated at 950, which is increased in the summer by visitors to some 3,000. Practically all of the inhabitants are served with the public water supply. The waterworks are owned by the Stamford Water Company, of which Judge J. P. Grant is president. The water supply is derived from the headwaters of the Delaware river on which a reservoir has been constructed and from two drilled wells which are used as an auxiliary source of supply. From the reservoir the water is delivered by gravity and from the wells the water is pumped through three pressure mechanical filters to the water mains. The consumption is estimated to vary from 100,000 to 300,000 gallons per day. Storage is provided in a reservoir formed by an earth dam.

The watershed area tributary to the surface supply is 1¼ square miles and consists of a moderately populated farming district with an estimated resident population of 24 per square mile. An examination of the immediate surroundings of the reservoir and of the creek show the possibility of considerable pollution entering the supply in surface wash from pastures and of direct contamination from cattle which have free access to the stream above the reservoir.

The filtration plant used for treating the well water is located approximately ¼ of a mile north of the village and is located in a wooden frame structure adjoining the pumping plant and wells. The filters consist of one Federal and two Continental Jewell pressure mechanical filters. The filters were overhauled in 1920 and new sand placed in them. Alum may be applied by means of the Shunt system, although the operator stated that the alum is not always used. The recent inspection was made as a result of a notice received by us that the regular water supply was becoming depleted and requesting the use of the Department emergency chlorination apparatus, as it appeared likely that it would be necessary to augment the supply by pumping from Churchill lake, an auxiliary supply, subject to considerable opportunities for pollution from residents and trespassers in the vicinity. Subsequent inspections were made at the request of the village authorities to furnish advice in the matter of the purification of the auxiliary supply. At the time of the inspection, on October 1, it was found that the water company had used the lake water without treatment from September 17 to 21 and from September 29 to October 1, inclusive, for approximately 10 hours per day and that pumping had begun on the day of the inspection at 6 A. M. The pump was delivering approximately 100 gallons per minute, and it was said that it was necessary to resort to the lake supply, as the regular supply had proven insufficient to meet the demands of the village.

At the time of the inspection it was found that the water company had repaired and cleaned out an old reservoir formerly used as an auxiliary source of supply, and it was learned that by the laying of a pipe line this source of supply would be available. Furthermore, the water company had erected a pumping station and purchased new pumping equipment for furnishing this supply to the village under pressure, as the reservoir is not at sufficient elevation to readily supply by gravity the water to the village. It was thought, therefore, that it would not be necessary to use the Churchill lake supply again. As a result of these conditions it was concluded that it would be useless to install the Department chlorination apparatus, as by the time the apparatus had been installed pumping would undoubtedly not be again necessary. The water company and the village officials were, however, instructed with regard to the use of hypochlorite of lime for emergency sterilization of the supply should it become necessary to pump from Churchill lake again. Directions were left for making the starch iodide test for excess chlorine and the water company were advised to dissolve 2 pounds of hypochlorite of lime in a 50-gallon barrel of water which should be connected by means of a hose or pipe to the suction line of the pump and a gate valve provided for regulating the application of the hypochlorite solution in accordance with the results of the starch iodide tests. On the basis of 12 hours, pumping at the estimated rate of 100 gallons per minute, it would be necessary to use approximately ½ barrel of this solution per day for applying chlorine at the rate of .6 parts per million. The water company was further advised to notify the health officer and this Department if it again became necessary to pump water from the lake. It was learned at the time of the inspection that the water company had engaged an engineer to study their problem and aid them in augmenting and improving the present supply.

In a report on an inspection dated December 31, 1921, the following recommendations were made:

> 1. That the previous recommendations made by this Department in regard to the use of alum, the careful operation of the filter plant, the installation of a chlorination apparatus and the maintaining of a careful patrol of the sanitary conditions on the watershed, be carried out in order that a water supply of good sanitary quality may be furnished the residents at all times.
>
> 2. That in case the water company retain the old reservoir, provisions be made for treating this supply by means of liquid chlorine in order that the supply may be of a safe sanitary quality for human consumption.
>
> 3. That should it again be necessary to resort to the use of Churchill lake, the water company provide for the sterilization of the auxiliary supply.

SUMMITVILLE

A reinspection of the public water supply of the hamlet of Summitville, Sullivan county, N. Y., was made by Mr. W. W. Young of this Division on October 31, 1921. A previous inspection of this supply was made in 1920 and the report thereon published in the Annual Report of the Department for that year.

Summitville is an unincorporated village about 33 miles southwest of Kingston and has a population of about 200. It is not provided with a sewer system or a public water supply other than the one provided by the railroad for restricted use. The supply provided by the railroad company is derived from a small mountain stream flowing through a steep ravine, entering the abandoned western Hudson canal at a point about 1½ miles south of Summitville. The water is collected in the reservoir formed by a dam about 100 feet in length, placed at a point on the ravine about ⅛ of a mile above a 6-foot culvert through which the stream passes before entering the canal. The reservoir is provided with a spillway about 10 feet wide and 8 inches deep. The water is conducted by gravity through a 4-inch pipe provided with an inclined perforated strainer about 5 inches in diameter, extending through the dam at the reservoir to three places.

namely, the railroad depot, the hotel opposite the railroad depot and the tank supplying the railroad locomotives. It appears from information furnished our representatives that the top of the pipe in this tank is above the overflow level of the water in the tank, so that when water is pumped into the tank from the canal by an emergency pump which is provided for this purpose, it cannot enter the water supply system from the reservoir.

The watershed above the reservoir has an area of about 1 square mile, is quite precipitous and heavily forested. A road passes parallel to the stream and crosses it in the upper section of the watershed. This road is extremely rocky and little used. The only house on the watershed is near Summitville about ⅛ of a mile from the stream tributary to the reservoir.

In a report on the supply, dated December 15, 1921, the following conclusions were made:

1. That while the need for carrying out the previous recommendations of this Department still remains, the authorities in charge of the water supply have not carried out these recommendations.
2. That the supply is subject to dangerous contamination from the wash from the highway on the watershed and from animals and chance visitors on the watershed.

It was, therefore, recommended:

> That the present supply be abandoned for drinking purposes and another supply of satisfactory sanitary quality be developed, or that satisfactory means of filtration or sterilization of the present supply be provided.

SYRACUSE

An investigation of the public water supply of the city of Syracuse was made by Mr. Earl Devendorf, a representative of this Department, on June 27, 28 and 29, 1921. A previous investigation of this supply was made by this Division in 1919, and a report thereon published in the annual report of the Department for that year.

Syracuse is a city of some 170,000 inhabitants, located in the central part of Onondaga county at the southeast end of Onondaga lake, and is a growing industrial and manufacturing center. The city is served by a comprehensive sewer system which discharges into the waters of Onondaga lake or its tributaries. The public water supply is owned by the city and operated by the bureau of water, of which Mr. William J. Apps is superintendent. The supply is derived by gravity from Skaneateles lake, some 19 miles southwest of the city, and is sterilized by means of liquid chlorine before being delivered to the distributing reservoirs located in the city. A history of the development of the present water supply was given in detail in our previous report, dated November 14, 1919, and reference is made to that report for this information.

The water supply is taken from Skaneateles lake at a point near the middle of the lake approximately 6,400 feet south from the north shore and in about 40 feet of water. The intake is about 20 feet from the bottom of the lake and is protected by a ¼-inch mesh copper screen. From this intake the water is conveyed by gravity through a 64-inch pipe to a screen chamber located on shore over which a stone building has been erected. In this building gates are provided for regulating the flow of water through the two 30-inch pipe lines leading to Woodland reservoir in the city. In the screen chamber a Wallace and Tiernan, manual control, chlorination apparatus has been installed and chlorine was being applied to the water at the rate of .3 parts per million at the time of the inspection.

Due to the recent growth of the city and the heavy increase in water consumption the two 30-inch conduits have, at times of maximum consumption, been overtaxed to such an extent that it was impossible to deliver the water to the standpipe due to the loss of head and consequent decrease in the capacity of the pipe line. The city has, therefore, installed an electrically operated pump which is used at times of heavy water consumption to pump the water to the standpipe and at these times water from both conduits is discharged directly into the Woodland reservoir. The gate house is provided with the necessary valves and connections for regulating and changing the flow to the reservoir and standpipe. From the Woodland reservoir two 36-inch and one 30-inch distributing mains supply water to the low pressure distribution system of the city and from the standpipe a 24-inch distributing main supplies the water to the high-pressure distribution system. From a record of the average daily consumption by months — from January 1920, to May 1921 — the total daily consumption varies from a minimum of 23,504,000 gallons to a maximum of 26,016,000 gallons, giving a minimum and maximum average daily per capita consumption of 136 and 153 gallons, respectively. In general the details of the water system remain as described in the previous report. It appears that the chlorination plant has been operated continuously since the last inspection in 1919, and that it has been the practice for the past 2 years to apply chlorine at the rate of about 0.1 parts per million during the winter and to increase the rate of application to about 0.3 parts per million each spring. Instead of changing the rate of application of chlorine as in the past, sufficient chlorine should be applied continuously to the water to give a slight excess of free chlorine by the starch iodide test in order to provide for the effective sterilization of the water supply of the city at all times.

Skaneateles lake, from which the supply is derived, is one of the smallest of the Finger lakes and is approximately 15 miles in length and 1 mile in width. On the watershed there is a total of some 900 houses. Some 273 of these houses are located along the shores of the lake and, for the most part, are used only during the summer months. The permanent resident population is estimated at 3,000, or approximately 50 per square mile. During the summer months this population is increased and is estimated at some 4,500, or approximately 70 per square mile. There is no large stream tributary to the lake, the majority of the tributaries being small streams flowing in from the side hills forming the valley in which the lake is located.

Rules and regulations for the sanitary protection of the water supply were enacted by this Department on November 25, 1907. It is found that the city carefully maintains an effective oversight and control of the lake and the watershed and rigorously enforces the rules and regulations. To this end the city employs 5 men during the summer months and 3 men the year round to daily patrol the shores of the lake in order to detect and eliminate any possible source of contamination that may exist on the watershed. The city owns 3 motor launches which the men use to collect the garbage and removable containers provided in the privies at the cottages located along the lake. The entire area is covered about once a week. The garbage together with the contents of the containers provided for the privies is disposed of by burial in a plot of ground owned by the city about ½ mile back from the head of the lake. Great care is taken in carrying out the above procedure and to see that the supply is not subject to any possibility of contamination. These precautions should be continued by the city authorities in order to insure a continuance of the present satisfactory quality of the lake water.

Formerly a number of passenger steamers were operated on the lake but these steamers have been abandoned and removed from the lake. There was also a summer resort known as Cliff Haven, formerly located at the south end of the lake. The city, however, purchased the land and removed the hotel and cottages and at present the land is occupied only by the caretaker employed by the city.

Under the present careful supervision of the city authorities there would appear to be little likelihood of any permanent sources of contamination being maintained on the watershed. In view of the use of the lake for pleasure purposes and the comparatively large number of summer visitors along the shores and upon the waters of the lake there is, however, more or less opportunity for contamination from the accidental, incidental or wilful pollution arising from boating and fishing on the waters of the lake. Furthermore, boating or fishing in the vicinity of the intake might occasion direct contamination of the supply. For these reasons the present effective sterilization of the public supply should be continued at all times. The city authorities should, however, purchase and install a duplicate chlorinator in order to insure the continuous application of chlorine at all times and to prevent any interruption in the chlorination of the supply due to the possible failure of the present apparatus to operate through breakage or for any other reason.

At the time of the inspection the city authorities were considering the construction of an additional conduit for a portion of the distance from Skaneateles lake to the city, in order to augment the capacity of the present conduits. The present conduits have a capacity of some 13,000,000 and 14,000,000 gallons, respectively, and, during times of maximum consumption, the capacity of these conduits is exceeded, due to a reduction of capacity on account of the excessive loss-of-head resulting from the high velocities in the conduits at the time of the high rates of consumption. It is planned to begin construction of the new conduit in the near future.

Some trouble was said to have been experienced this year as in the past from tastes and odors existing in the water. During this year the tastes and odors lasted for a period of about one week, but these conditions had, however, disappeared at the time of the inspection. The matter of cross-connections of the public water mains with any auxiliary fire supplies was taken up with the city authorities who were of the opinion that all such cross-connections had been removed. Information obtained from the Underwriters' Association, however, indicates the possibility of cross-connections existing at the Will Brennan Candle Company's factory, located in the town of Onondaga, the Cross Hines factory on Wolf street and at the Franklin Automobile works. The city authorities should ascertain if there are any cross-connections at these factories or elsewhere between the public mains and any auxiliary fire supply and cause their complete severance or the installation of double check valves in accordance with the plans approved by this Department.

In our previous reports it has been recommended that the city authorities continue their careful and diligent oversight of the sanitary conditions at the lake and upon the watershed; that chlorination be carried on at all times and that studies be made of aeration of the supply and the application of copper sulphate in order to reduce the trouble caused at certain times of the year by algæ growths. From the recent inspection it appeared that the city authorities have carried out the former recommendations with regard to applying the chlorine continuously and are maintaining a most thorough and careful control and oversight of the sanitary conditions both at the lake and upon the watershed in order to prevent any possible chance contamination of the supply and that some studies have been undertaken with a view to reducing the trouble from algæ growths.

In a report upon the supply, dated August 26, 1921, it was recommended:

1. That the city authorities continue their present very careful supervision of the sanitary conditions at the lake and upon the watershed strictly enforcing the rules and regulations enacted by this Department.
2. That liquid chlorine be applied to the public water supply continuously in sufficient quantities to properly sterilize the water and give a slight excess of free chlorine by the starch iodide test at all times.
3. That a duplicate chlorination apparatus be purchased and installed at the gate house in order to insure the continuous sterilization of the public water supply.
4. That the city authorities make a survey of the present distribution system to discover any cross-connections of auxiliary fire supplies with the public mains and eliminate them or provide for the installa-

tion of double check valves in accordance with the plans approved by this Department.

5. That as previously recommended the city authorities should continue studies of aeration of the supply and the application of copper sulphate in order to reduce the trouble caused by algæ growths.

THENDARA

A reinspection of the public water supply of the village of Thendara, was made by Mr. Earl Devendorf, a representative of this Department on August 25, 1921. A previous investigation of this supply was made by the Division in 1920 and the report thereon published in the Annual Report of the Department for that year.

Thendara is an unincorporated village located in the central part of Herkimer county about 40 miles north of Utica and on the Moose river. The resident population at the time of the inspection was estimated at 400, practically all of whom are furnished with the water from the public water supply as well as the additional summer population estimated at 100. The waterworks are owned and operated by Mr. Lyon DeCamp. The water supply is derived from springs located on a hill three-quarters of a mile west of the New York Central Railroad station. From the small reservoir the water is led to the village where it is distributed through some two miles of water mains. Little or no storage is provided. The watershed tributary to the supply is wholly uninhabited and no permanent sources of pollution exist on the watershed.

In a report on an inspection of the supply dated October 17, 1921, the following conclusions were made:

1. That the authorities in charge of the water supply have endeavored to carry out the previous recommendations of this Department in carefully supervising the supply and making frequent inspections of the watershed in order to discover and eliminate any possible source of pollution that may be found to exist.

2. That during periods of cold weather when the inhabitants allow the faucets to remain open to prevent freezing, the supply is depleted, and during the summer season with the increased summer population, the supply is at certain periods of maximum consumption throughout the day also depleted, and at times wood dirt from the reservoir is drawn through the faucets.

It was therefore recommended:

1. That the authorities continue their careful supervision of the supply making frequent and careful inspections of the watershed to prevent any contamination of the public water supply.

2. That the authorities clean the small intake reservoir frequently in order to prevent any large accumulation of wood dirt that will enter the public mains and increase the present storage capacity of the reservoir in order to provide an adequate supply at times of maximum consumption.

THERESA

A reinspection of the public water supply of the village of Theresa, Jefferson county, N. Y., was made by a representative of this Department on September 21, 1921. Previous inspections of this supply have been made in 1911, 1915, 1918 and 1919, and the reports thereon published in the Annual Reports of the Department for those years.

Theresa has a present population estimated at about 900 and is located on a bluff at the falls of the Indian river, 96 miles from Utica and 98 from Syracuse. About 90 per cent of the total population are served with the public water supply. The waterworks are owned and operated by the municipality under the direction of the water commissioners; Mr. E. M. Wheeler is superintendent and the pumping plant is operated by the Farmers Milling Company. The water supply is derived from a pond in Indian river near the center of the village. The water is delivered by pumping through the distribution system. The average daily water consumption is approximately 45,000 gallons. The watershed tributary to the supply embraces about 313 square miles and contains a population of about 22 per square mile. This population is, however, largely widely scattered and remote from the main stream except for the villages of Philadelphia and Antwerp. These two villages together contain about 2,000 persons, and considerable sewage from these places is discharged directly into Indian river. In the village of Theresa there are specific sources of contamination from about 30 houses which are located along a street at the top of the steep bank of the river on the north side of the village. Four or more of these houses have flush toilets. Many or all of these dwellings discharge their sewage either directly upon the narrow flat below the bank or upon the steep slope leading to this flat. In addition at times of high water this narrow flat is flooded by the stream. There are one or two lakes and other possible sources of water supply within 3 or 4 miles of Theresa and the moving of the pumping station a mile up-stream has been discussed; but no action taken. The plant for the sterilization of the water was installed about a year and a half ago but was not in operation at the time of the inspection due to the exhaustion of the only cylinder of chlorine purchased and to the stoppage of the small screen. A new chlorine cylinder was reported to have been ordered and a larger screen was being installed. It was claimed that the public supply is used for potable purposes by only about 10 per cent of the population, and that the remainder depends upon wells for drinking water.

In a report on an inspection of the supply dated October 6, 1921, the following conclusions were made:

1. That while the need for carrying out the previous recommendations of this Department still remains, the authorities in charge of the water supply have carried out these recommendations only in part.
2. That there remain certain opportunities for dangerous infection of the supply.
3. That the chlorine apparatus was not in operation at the time of the inspection.

It was therefore recommended:

1. That the municipal authorities in charge of the water supply carry out at once such of our previous recommendations as have not as yet been acted upon.
2. That the village provide scales and spare parts for the chlorination and extra cylinders for the chlorine apparatus to insure the continuous chlorination of the supply.
3. That starch iodide tests be made daily to determine the amount of chlorine to be applied.
4. That the people be warned to boil the water in the case of interruption of the chlorination of the supply.

TICONDEROGA

A reinspection of the public water supply of the village of Ticonderoga was made by Mr. Earl Devendorf, a representative of this Department on June 2, 1921. Previous inspections of this supply have been made by this Division in 1906, 1907, 1913 and 1918 and the reports thereon published in the Annual Reports of the Department for the respective years.

Ticonderoga is an incorporated village with a present population estimated at 2,200 and is located in the southeastern portion of Essex county between Lake George and Lake Champlain, 100 miles north of Albany. Ticonderoga creek which connects Lake George with Lake Champlain also flows throug the village. Some 3,500 people are served with the public water supply a the mains extend outside the village limits. The waterworks are owne and operated under a board of trustees of which Mr. Albert Weed is presiden

The water supply is derived from two main sources of supply; brooks an springs feeding to a reservoir on Chilson Hill, and two intakes, gravity an suction, on Lake George in the southerly part of the village. From the Chi son Hill reservoir and from the intake south of the bridge at Lake Georg water is supplied by gravity through 12 to 15 miles of water main The Chilson Hill supply mains and the Lake George gravity mains are lai parallel in many streets and so arranged that the gravity Lake Georg system in most cases can be used in emergencies. In general the detai of the waterworks system remain as described in the previous reports.

Since the last previous inspection, no attempt has been made to impro the sanitary conditions existing on Chilson Hill brook above the poin of intake. The privy of the caretaker's house at the reservoir is located s close to the reservoir as to constitute a source of potential danger and ha not been removed as previously recommended. Some attempt has been mad to devolop the Chilson Hill spring reservoir. It was noted that the basi surrounding this spring was not watertight and allowed surface wash t enter, and the area in the immediate vicinity of the springs was open t the cattle grazing on the land where the springs were located. The pipe lin leading from the spring to the reservoir emptied into a wooden barrel alon the path above the caretaker's house, from which point the water flowe to the reservoir through another pipe line. At the time of the inspectio this second pipe line was broken and the water was flowing from the barr to the reservoir over the surface of the ground. The Chilson Hill reservoi water is first passed through a bed of coke before entering the mains lea ing to the village. The watershed tributary to the Chilson Hill supply is som 4.5 square miles in area and consists of a small populated farming distri with a resident population of 16.6 per square mile. Opportunities for indire pollution of the water supply streams by surface wash from the vicinit of farm houses, barns, and cultivated fields are numerous. In one case ther is danger of surface wash from a barnyard about 150 feet from the broo flowing directly into the stream. The houses located on the south side the brook where the banks are steep are also sources of possible contaminatio

With reference to the Lake George supply, the supply is subject, a pointed out in the previous reports, to the continuous as well as intermitte pollution from nearby dwellings and boat houses. The sanitary conditio in Alexandria which lies just outside the southerly corporate limits of th village, and below which the intake of the supply is located are decided bad, and constitute a serious potential danger to the water supply. Ther is no sewerage system in Alexandria, and the drainage leads directly towa the lake. Drainage from houses on the street parallel to the lake collects i the gutters and also eventually finds it way into the lake. At Reed's garag however, the privy was said to have been removed. A toilet in the adjace house is connected with a cesspool said to be located in the rear of th lot which abuts on the lake.

In a report on an inspection of the supply dated October 17, 1921, th following conclusions were made:

1. That the authorities in charge of the water supply have not carrie out the previous recommendations of this Department.

2. That as pointed out in the above report, opportunities for serio and potentially dangerous contamination of both the Chilson Hill a Lake George supply remain, and in their present state they cannot considered safe for domestic consumption without some form purification.

It was therefore recommended:

1. That the authorities in charge of the water supply carry out once such of our previous recommendations as have not yet been act upon.

2. That the auxiliary spring at Chilson Hill be improved as outlined in the body of the report on the inspection:

(a) By raising the curb to exclude surface wash.

(b) By enclosing with a tight fence to prevent trespassers or cattle from coming in the vicinity and causing any possible pollution.

(c) By the construction of drainage ditches to divert surface wash from the vicinity of the spring.

(d) By replacing the broken pipe line leading from the spring to the reservoir and eliminating the wooden barrel receiving the spring water before it enters the reservoir.

3. That the caretaker's privy at the Chilson Hill reservoir be removed to a point not less than two hundred feet from the reservoir, and the contents frequently removed and disposed of at a point remote from the reservoir, stream and springs in order that there may be no opportunity for pollution of the supply.

4. That the authorities in charge of the public water supply endeavor to divert barn and house drainage from the Chilson Hill reservoir feeders and should any trouble be experienced in carrying out the above recommendations the authorities should make application to this Department for the enactment of rules and regulations for the sanitary protection of the public water supply.

5. That the Lake George supply be abandoned or that the intake be extended to a point above Alexandria and provide at least for the chlorination of this supply whenever used.

6. That in view of the present unsatisfactory conditions of the water supply of Ticonderoga, necessitating the immediate improvement of the supply and in view of the intricate and detailed questions involved, the village should employ a competent sanitary engineer to study the situation and determine the most feasible and economical means for providing a supply which will be both adequate in quantity and of a satisfactory sanitary quality at all times.

TULLY

A reinspection of the public water supply of the village of Tully, Onondaga county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on December 13, 1920. A previous inspection of this supply was made by this Division in the year 1916 and the report thereon published in the Annual Report of the Department for the year 1917.

Tully is located about 22 miles south of Syracuse and has a population of 600, of which 85 per cent is served by the public water supply. The waterworks are owned and operated by the village under the direction of the water and light board, of which Mr. R. H. Wheeler is president. The water supply is derived from a dug well located in the eastern part of the village from which it is pumped directly into the distribution system.

The sanitary conditions surrounding the well are not entirely satisfactory. There is one house within 100 feet of the well. The house nearest the well had a privy which was in a very insanitary condition at the time of the inspection. Since the previous inspection the well has been concreted and better protected from surface wash and a new building constructed to house it. The previous recommendations of the Department in regard to development and fencing of the new well, have not been carried out.

It was therefore recommended in a report dated February 1, 1921:

1. That the authorities in charge of the public water supply develop a new supply at a point not less than 500 feet east of the present well.

2. That an area at least 200 feet in diameter be fenced in around the well and that trespassing within this enclosure be forbidden.

3. That, pending the development of a new supply, a chlorinating apparatus be installed to sterilize the present supply.

4. That frequent tests be made of the chlorinated water for exc chlorine in accordance with the directions issued by this Department a the rate of application of the chlorine regulated in accordance with t results of these tests.

TUXEDO PARK

A reinspection of the sanitary condition of the public water supply Tuxedo Park was made by Mr. W. J. Erickson, sanitary engineer in tl Department, on December 10, 1920. Previous inspections were made of tl supply in 1908 and 1915 and are reported upon in the Annual Reports this Department for the respective years.

Tuxedo Park is a residential park surrounding Tuxedo lake, which l in the southerly point of Orange county, near the Rockland county li The small community to the east of the park is known as the village. T park has a summer population of about 2,700 which is reduced to appro mately 300 in winter. The village has a permanent population of abo 1,200. The park is controlled by the Tuxedo Park Association. It is pr vided by a private sewer system which discharges the sewage into a bran of the Ramapo river after treatment. The disposal plant consists of septic tank, coke and sand filters. The sewers in the vicinity of Tuxe lake, which is the source of the water supply, are of cast-iron laid with le joints. The water supply is controlled by the Tuxedo Water Company, f which Mr. Lorillard is president. The supply is delivered to the consume through two systems, namely, the park system and the village system. T supply for the park system is delivered by pumping from the lake throu the distribution system to a standpipe. An auxiliary pump has be installed to supply the park property on the west side of the lake. The co sumption averages about 1,500,000 gallons in summer, but due to the small population in winter the consumption falls considerably during these montl The village system is supplied by gravity from the lake to the distributi system. The consumption in the village is not definitely known but probably about 500,000 gallons a day.

The intake for the village supply is located at the northern or lower e of the lake at the dam. The intake extends 300 feet into the lake at depth of 10 or 15 feet. The water is siphoned over the dam and then flows by gravity to the village. The main pumping station for the Pa system is located on the eastern shore of the lake. The intake extends feet out into the lake, where the water is about 35 feet deep and is held trestles at about 10 feet below the surface. An auxiliary intake has be laid at the dam near the village intake extending into the lake for a distan of 400 feet. To provide water for two residences in the higher area in t western part of the park an auxiliary intake has been extended into the la for 300 feet in the western part of the lake. The water is pumped into small concrete reservoir.

The lake has an area of about 288 acres and a watershed of about 4. square miles. The population on the watershed is about 700 which increased to about 1,700 during the day by laborers and gardeners on t estates. The resident population is therefore about 150 and the tempora population about 300 per square mile. Approximately 70 per cent of t area tributary to the lake is wooded. The major portion of the populat portion of the park is to the east and north of the lake. The park is la out in large estates and the houses are considerably scattered and few a near the lake. All houses are connected with the private sewer system a no sewer is nearer than 30 feet of the lake. These sewers are constructed cast-iron pipe. Unless there should be an overflow from these sewers, due clogging or breakage, there should be no danger of pollution of the supp from this source.

The roads skirt the lake shores at several points, especially at the base Eagle mountain. It is said that these roads are swept daily and that tl sweepings are carried away to a safe point of disposal. The rules are ve strict as to use of the lake. No bathing is allowed under the penalty of a heavy fine. Fishing is also regulated to certain zones and permitted only to the owners and their guests.

In a report on an inspection of the supply dated January 25, 1921, the following conclusions were made:

1. That the water supply of Tuxedo Park is subject to intermittent contamination incidental to operation of workmen in the fields, from surface runoff from these fields and roads along the lake, and from fishermen and boatmen on the lake.
2. That the analyses of the samples of water taken at the time of the inspection showed the presence of some active contamination.

It was therefore recommended:

1. That the water company continue to exercise strict supervision of the supply at all times in order to assure a water of satisfactory sanitary quality.
2. That the authorities install and efficiently operate a suitable apparatus for the sterilization of the supply with liquid chlorine.

UNADILLA

A reinspection of the public water supply of the village of Unadilla, Otsego county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on March 2, 1921. A previous inspection of the supply was made by this Division in the year 1916 and a report thereon published in the Annual Report of the Department for that year.

Unadilla is located about 17 miles southwest of Oneonta and has a population of 1,200, of which 85 per cent are served by the public water supply. The waterworks are owned and operated by the village under the control of the water board of which Dr. S. J. White is president.

The water supply is derived from Kilkenny springs about a mile north of the village and from Martin brook, about 2 miles north of the village. An auxiliary supply is derived from wells northwest of the village. The two main supplies are entirely separate, serving different sections of the village, although either one may be made to serve the entire village. The water is delivered by gravity to the distribution system.

The Kilkenny supply is derived from 7 springs located near a hill of forested, uninhabited land. The Martin brook supply has a drainage area above the intake of about 2 square miles of agricultural and forested land. There are 12 farm houses on the watershed of the brook. Although the sanitary conditions on the watershed were in general satisfactory, there is always a possibility of indirect pollution of the supply from the farm houses and chance or wilful contamination from trespassers. The 4 driven wells which comprise the auxiliary supply are located near a built-up section of the village. There is a cesspool within 200 feet south of the well and 5 privies within 500 feet of the well. The other 3 wells are located in an open field away from inhabitation, the surrounding land being owned by the village.

The recommendations of this Department in regard to sterilizing the Kilkenny and Martin brook supplies with liquid chlorine and the abandonment of one of the auxiliary wells, have not been carried out.

In a report dated March 29, 1921, on an inspection of the supply the following recommendations were made:

1. That the present strict supervision of the watershed be maintained and that all sources of pollution be removed.
2. That the north wall of the lower reservoir of the Kilkenny supply be extended about a foot above the ground to exclude surface wash.
3. That the drainage from the highway in the Martin brook watershed be diverted so as not to enter the public water supply.

4. That suitable apparatus be installed for sterilizing the supply wit chlorine. preferably at some central point, and that chlorine be applie in the water in proper quantities at all times.

5. That frequent tests be made of the chlorinated water for exce chlorine in accordance with the directions issued by this Departme and the rate of application of the chlorine regulated in accordance wit the results of these tests.

UNIONVILLE

A reinspection of the public water supply of the village of Unionvil was made by Mr. W. J. Erickson, sanitary inspector in this Department, o May 12, 1921. Previous inspections were made of this supply in 1908 ar 1915, the reports on which are published in the Annual Reports of th Department for the respective years.

Unionville is an incorporated village with about 400 inhabitants located i the southwestern part of Orange county. It is 12 miles from Middletow about ½ mile from the New Jersey border. The public water supply is owne by the Unionville Water Works Company of which Dr. E. A. Nugent is pres dent and Mr. Floyd Terry superintendent. The village is not provided wit a public sewer system. The supply is derived from two driven wells locat south of the village. A small covered reservoir has been constructed over th wells from which the water is pumped through the distribution system to th storage reservoir. The consumption is estimated to be about 40,000 gallo per day. The reservoir is on the side of the hill in the eastern part of th village. It is formed by two dams across a small gully in the hil side. The wells are drilled in the built up section of the village in a lo flat area. There are ten or more houses within 500 feet of the wells, th nearest being about 200 feet away. A stream emptying into the Wallkill flo alongside of a street on the opposite side of which there is a row of hous and passes about 20 feet from the well. Several house drains empty int this stream as does the exhaust from the silk mill located above the well The stream passes under the railroad embankment below the wells in a culve which is too small to adequately carry off the storm of the stream and caus a flooding of the area in which the wells are located.

The mill of the American Silk Label Manufacturing Co., is located abou 150 feet from the wells. The sewage is taken care of by chemical toilets whic discharge into two-150 gallon iron tanks. These tanks are emptied and th contents drawn away as often as necessary. The plant is to be enlarged b the construction of new buildings so as to accommodate about 200 employee As trouble is being experienced from the present method of disposal, a ne system is desired. On account of the impervious nature of the soil it is im practicable to dispose of it by leaching cesspools or subsurface irrigation an discharging it into the stream except in a completely treated state. The are above the upper reservoir has been fenced and drainage ditches to divert su face wash from cultivated fields above the reservoir, have been constructe Several small springs issue from the ground inside of the enclosure and ar used to augment the supply. Algæ growths were developing in the reservoi especially along the edges.

In a report on an inspection of the supply dated June 6, 1921, the followin conclusions were made:

1. That the location of the wells in a comparatively thickly settle village is very unsatisfactory.

2. That the ground water tributaries to the wells are highly pollute from the numerous privies and cesspools in the village and that ther is no assurance that these wells will not at some time become activel and dangerously contaminated.

3. That the wells are further subject to serious contamination from th small polluted stream passing near them at times of high water when i is possible that the creek water seeps through the porous concrete block

4. That, while the upper reservoir is protected from direct surface wash, the area above the reservoir should not be used for pasturage and should not be fertilized with any manure as such action could probably effect the sanitary quality of the springs.
5. That the water supply is depreciated by the presence of heavy algæ in the reservoir.

It was therefore recommended:

1. That in view of the polluted condition of the ground water tributary to the well supply, that the water company secure a new supply of unquestionable sanitary quality and adequate in quantity.
2. That pending the development of a new supply, the present supply be sterilized with a liquid chlorine.

UTICA

A reinspection of the public water supply furnished by the Consolidated Water company of Utica to the city of Utica and a number of villages and towns in Oneida county, was made on July 20, 1921, by Mr. A. I. Howd of this Division accompanied by Mr. George C. Hodges, biologist for the company. A previous investigation of this supply was made on May 27 and 28, 1918, and the report upon the investigation was published in the Annual Report of the Department for that year.

The city of Utica, which has a population of 94,156 according to the census of 1920, is located in Oneida county in the central part of the State.

The water supply of the Consolidated Water Company of Utica is derived from a number of sources, but for simplicity may be combined into two groups, a northern supply, which furnishes about 75 per cent of the water used and a southern supply, which furnishes the remainder, or about 25 per cent of the water used in the city and neighboring villages. The northern supply is derived principally from the west Canada creek, at times augmented by water from Reels creek. The southern supply is derived from a number of small streams south of the city.

In addition to furnishing the city of Utica with water, the Consolidated Water Company of Utica supplies the villages of Oriskany, New Hartford, Whitesboro and Yorkville, the towns of New Hartford and Whitestown, part of the town of Deerfield, and the unincorporated village of New York Mills (which is in the towns of New Hartford and Whitestown). The total population served with water by the company is about 125,000. In addition to the water furnished for domestic consumption, water is supplied to a number of industrial plants and to several railroads, namely, the New York Central, the Delaware. Lackawamna and Western, the New York, Ontario and Western and the West Shore and is used by them in filling tanks on coaches and diners for drinking purposes, as well as for boiler and other purposes. The average total daily water consumption for 1920, according to the records of the company, was 11.6 million gallons, of which 9 million gallons was obtained from the northern supply and 2.6 million gallons from the southern supply. The maximum daily water consumption occurred during June and was 12.4 million gallons while the minimum daily water consumption occurred during December and was 9.8 million gallons.

The northern supply is taken from the West Canada creek at Hinckley, about 17 miles north of Utica, where a dam has been constructed across the creek forming a reservoir which has a capacity of 25,500 million gallons and a water surface area of 2,820 acres. The water flows from the reservoir by gravity through about 12 miles of 24-inch pipe to the Marcy standpipe where it is diverted to two distributing reservoirs, the Marcy reservoir about 2 miles below and the Bacot (Deerfield) reservoir about 4 miles below the standpipe. Water from an intake in Reels creek is also discharged into the Bacot reservoir. Both the Marcy and the Bacot reservoirs are open and formed by earth embankments, the inner slopes of which are paved. The

Marcy reservoir has a capacity of 15 million gallons and the Bacot reservoi has a capacity of 106.5 million gallons. The water is chlorinated and metere as it leaves each of the reservoirs. The supply from the Marcy reservoi enters the northwestern part of the city about 4 miles below the reservoi and the supply from the Bacot reservoir enters the city at Genesee stree about 3 miles below the latter reservoir.

The system comprising the southern supply consists principally of a numbe of impounding and distributing reservoirs. A dam constructed across small stream about 4 miles south of the city impounds the water and form what is known as reservoir No. 1. This reservoir which is also fed b springs, furnishes water directly to the New Hartford district. Reservoi Nos. 2, 4, and 5 are located close to each other near the southeastern edg of the city. An intake on Starch Factory creek furnishes water to reservoir Nos. 2 and 5 while No. 4 impounds a small stream. The water from No. and No. 5 may be pumped into No. 4. The water company is contemplatin certain changes and additions to their distribution system whereby the entir population served with water may be furnished with water solely from th northern supply. The southern supply will then be retained as an emergenc auxiliary supply.

The several water supplies which reach the general distribution system ar treated with liquid chlorine. A chlorination and meter house is located a the foot of the Bacot reservoir. The building is constructed of tile and ma be heated. The chlorinator now in use was installed about two years ago was manufactured by Wallace & Tiernan Company, Inc., and is of the automatic control dry feed type. The Venturi meter recorded at the time o the inspection a flow of water at the rate of 6.1 million gallons daily, an the manometer on the chlorinator indicated the application of chlorine at th rate of 25½ pounds per 24 hours, or about 0.50 parts of chlorine per millio parts of water.

A chlorination and meter house is also located below reservoirs Nos. 2, and 5. The Venturi meter on the line from reservoir No. 1 showed a flow a the rate of 1.25 million gallons at the time of the inspection, while the Venturi on the discharge from reservoirs Nos. 2, 4 and 5 showed a flow at th rate of 1.2 million gallons. The especially designed chlorinator to treat th water from reservoirs Nos. 2, 4 and 5, consisting of a large concrete solutio tank, has been replaced by an automatic control dry feed chlorinator manufactured by Wallace & Tiernan Company, Inc. The scales which are provide for weighing the chlorine cylinders were being repaired and out of servic The small glass tube in the manometer had apparently become loosened an dropped to the bottom of the manometer, which was not recording at the tim of the inspection. Owing to severe storms preceding and during the inspectio it was impossible, due to the condition of the roads, to visit the Marcy reservoir and reservoir No. 1 and their chlorination plants.

Rules and regulations for the protection from contamination of the publi water supply of Utica were enacted by this Department in 1907. The rule apply to the watershed of West Canada creek above the dam at Hinckley an the watershed and reservoirs of Reels creek, on the northern supply, and t Ballou creek, and Starch Factory creek watersheds and reservoirs, on th southern supply. The West Canada creek above the intake for the Utic water supply at Hinckley has a watershed area of about 375 square mile The watershed is quite heavily wooded and sparsely populated, the populatio on the shed being estimated at about 1,500, or 4 per square mile. The northern watershed is patrolled in sections for about 20 miles above the intake, an the southern watersheds are patrolled continually. Tight containers are provided by the water company for privies and for slops from properties nea streams on the watersheds, and the company attends to emptying the containers and disposing of the contents at remote places so as not to pollut the supply.

The last previous report of this Department recommended that the wate company carefully patrol the watersheds of various supplies and vigorousl enforce the rules and regulations; that the supplies be at all times efficientl sterilized; that a more satisfactory apparatus be installed at the Marcy rese voir and duplicate equipment be provided at the New Hartford supply; and that the action already started toward the protection of the water in the distribution mains from pollution through cross-connections be continued either by the complete severance of the auxiliary mill supplies, or by the installation of properly designed double check valves and gates located in accessible manholes, and, in the case of double check valve installations, regular and frequent inspections be made to determine the satisfactory operation of these safeguards.

As a result of the present inspection, it appears that the recommendations of the previous report in regard to patrolling watersheds, enforcing rules and installing a more satisfactory sterilization apparatus at the Marcy reservoir, have been carried out. As far as could be learned, no further action has been taken, however, by the city or water company to require either the complete severance of the auxiliary mill supplies or the installation of properly designed double check valves and gates. No further inspections have been made of the cross-connections between the city mains and auxiliary supplies since the inspection of Marmaduke Owens for the Consolidated Water Company on December 10, 1917.

The matter of permitting only proper and safe cross-connections between the public water supply mains and those of auxiliary supplies for industrial plants is of the utmost importance. Immediate action should be taken to require a severance of all improper and unsatisfactory connections, or the installation of properly designed double check valves and gates located in readily accessible manholes outside of the buildings and near the municipal mains. The installation should be of the type approved by this Department or a type fully equivalent thereto. A test should be made at monthly intervals of the tightness of the check valves, and at least once each year the bonnets of the check valves should be removed and the checks and their bearing seats carefully cleaned. In this connection also, all existing interior service lines should be disconnected from such fire lines running from sprinkler or hydrant feeders and taken off from the public mains on the city side of the check valves.

In a report upon the supply dated December 19, 1921, it was recommended:

1. That the Consolidated Water Company continue their careful supervision over the watersheds of the streams from which the water supply is derived, and enforce the rules and regulations for their protection.
2. That careful attention be given to the maintenance of the various chlorination apparatuses, so that they may be operated effectively and efficiently at all times.
3. That the water company consider the installation of duplicate chlorination apparatuses at all points where chlorine is applied to the water, to preclude the possibility of any interruptions in the chlorination of the supply.
4. That an ample supply of chlorine be kept on hand at all times.
5. That, in order to eliminate the possibility of contamination of the public water supply through cross-connection with auxiliary industrial supplies, such as occurred in 1917, the Consolidated Water Company require either a complete severance from their mains of the auxiliary industrial water supply from polluted sources, or the installation of properly designed double check valves and gates of the type approved by this Department or a type fully equivalent thereto.
6. That the water company institute a regular systematic and frequent period of inspection of the check valves in order to insure their proper operation at all times.
7. That the Consolidated Water Company of Utica carry out as soon as possible the proposed changes in their distribution system whereby the entire population served with water may be furnished with water from the northern supply, the southern supply to be retained as an emergency supply.

WALDEN

A reinspection of the sanitary condition of the public water supply of the village of Walden was made by Mr. W. J. Erickson, sanitary inspector, on March 15, 1921.

Previous inspections of this supply were made in 1909, 1913 and 1915, the reports upon which are published in the Annual Reports of this Department for the respective years.

The village of Walden is located in the northern part of Orange county, 10 miles northwest of Newburgh. Practically all of the village is served by a comprehensive sewer system, which empties through five outlets into the Wallkill river. Of the 5,100 inhabitants of the village, about 4,700 use the public water supply, which is owned and operated by the village under the direction of the board of water commissioners, of which Mr. E. B. Wooley is president. The water is derived from 9 driven wells, located about a mile south of the village, and pumped into a distribution system, consisting of about 10 miles of mains. The average daily consumption is 114,577 gallons. The wells near the center of the village have been abandoned, and the supply is derived solely from those outside of the village. These wells are located in a level area southwest of the village. The watershed tributary to the wells is about ¾ of a square mile in area and is sparsely populated. The village owns considerable land around the wells, which is unoccupied and fenced. The soil is largely of a gravelly nature underlain with a layer of blue clay. The water-bearing gravel from which the water is derived is under this clay strata. The wells are 6 inches in diameter and driven to a depth of 150 feet. The water is siphoned from the wells into a circular suction well. Each well is protected by a concrete box, which prevents the surface water from reaching the well casing. There are no sources of pollution in the vicinity of the wells.

In a report on an inspection of the supply dated March 25, 1921, the following conclusions were made:

1. That the public water supply of Walden, as derived from the wells located outside of the village, is apparently of satisfactory sanitary quality.
2. That the village has taken commendable action in having the former recommendations of the Department carried out.

It was recommended that the board of water commissioners continue their careful supervision of the water supply.

WARWICK

A reinspection of the public water supply of the village of Warwick, Orange county, N. Y., was made by Mr. N. H. Baier, sanitary inspector of this Department, on April 25, 1921. A previous inspection of the supply was made in 1913 and the report thereon published in the 34th Annual Report of the Department.

Warwick is located about 29 miles southwest of the city of Newburgh, and has a population of 2,800, 95 per cent of which are served by water from the public water supply. The waterworks are owned and operated by the village under the control of the board of trustees, of which Mr. John M. Demming is president. The water supply is derived from a small brook impounded in 3 reservoirs about 2 miles south of the village from which it flows by gravity to the village.

The stream above the reservoirs has a drainage area of about 1½ square miles of steeply, sloping, cultivated and forested land. The sanitary conditions on the shed are in general satisfactory, there being no dwellings from which human pollution may reach the supply. Horses and cattle are watered in the upper branches of the brook. The watershed is regularly inspected about twice a month. It appeared at the time of the inspection that fishing was prohibited in the reservoir. The reservoirs contained considerable vegetation and it was learned that fishy tastes are noticeable in the water at times.

The previous recommendations of this Department in regard to filling in cesspools on the Hitchcock farm, the provision of watering troughs or small ditches for cattle and the enactment of rules and regulations for the protection of the watershed have been carried out.

It was, therefore, recommended in a report dated May 9, 1921, on an inspection of the supply:

> 1. That the watershed be regularly inspected and the rules and regulations enacted by this Department strictly enforced, including those prohibiting fishing in the reservoirs.
>
> 2. That if it is found impracticable to obtain a water of satisfactory quality by controlling the area tributary to the reservoirs and rigidly enforcing the rules and regulations, apparatus for the sterilization of the supply be installed and put in operation.
>
> 3. That the reservoirs be, as far as possible, cleaned of vegetation and that copper sulphate be applied in proper quantity and under careful supervision at the first appearance of algæ growths to prevent their growth and the occurrence of tastes and odors.

WARD LANE

An inspection of the public water supply of the Ward Lane, Colonie, Albany county, N. Y., was made by Mr. W. J. Erickson, sanitary inspector, on June 8, 1921. The Ward Lane Water company, of which Mr. John Keeler is president, serves a small section of the town of Colonie adjacent to the city of Albany. The supply is delivered to about 7 or 8 houses of Ward Lane, Mid City park and a few industrial concerns, among them the Federal Signal company and the Simmons Machine company.

The supply is derived from a reservoir formed by a dam across a small brook about a half mile west of the main Albany-Troy highway just north of the Albany city line. The dam which is constructed of earth with a concrete core is about 150 feet wide and 30 feet high and forms a reservoir about 150 feet wide and 400 feet long. The reservoir though shallow near the shore is deep at the middle. Though the water was clear some algæ and weeds were observed near the shore. The watershed tributary to the reservoir is about three-quarters of a square mile in area. The summer residence of John Keeler is located south of the reservoir. This place is maintained in a satisfactory condition and the cesspool is located below the reservoir. There are in all about 10 houses on the watershed and a total population of about 50 or 60 per square mile. Most of these houses are on the upper part of the shed on the Loudonville road. The major part of the watershed is used for pasturage. Two main highways out of Albany also pass across the watershed, besides the possibility of contamination from a populated watershed, from pasture land and road wash.

In a report on an inspection of the supply dated July 11, 1921, the following conclusion was made:

> That the water supply of the Ward Lane Water company is subject to contamination by drainage from a populated watershed, from pasture lands along the stream and from 2 roads crossing it and also to incidental contamination by visitors on the shed.

It was therefore recommended that the water company either install a modern purification plant or abandon the present supply and develop a new supply of satisfactory sanitary quality.

WATERLOO

A reinspection of the public water supply of the village of Waterloo, was made by Mr. Earl Devendorf, a representative of this Department, on October 25 and 26, 1921, with special reference to the question of the occurrence of tastes and odors in the public water supply. Previous inspections of the supply have been made by the Division in 1909, 1915 and 1918 and the reports thereon may be found in the Annual Reports of the Department for the respective years.

Waterloo is an incorporated village with a population of some 4,500 inhabitants and is located in the northern part of Seneca county on the Seneca river. The waterworks are owned by the Waterloo Water Works company, of which Mr. William A. Wilcox is president. The water supply is derived from the Seneca river which has in recent years been dredged and improved by the State of New York and is now used as a part of the system of the new Barge canal. The intake of the water supply formerly was laid along the Seneca river to a point above Black brook but it was stated that at the time the Barge canal was constructed and the river dredged the intake pipe was disturbed and put out of service. The intake is now located near the westerly limits of the village from which the water flows by gravity into a sedimentation basin provided with baffles and is normally treated with alum prior to sedimentation. From the sedimentation basin the water flows to a collecting well from which the water is pumped to the 2 Roberts' pressure mechanical filters before being discharged into the distribution system. The excess over the consumption is stored in an elevated steel storage tank near the pumping station. The average daily water consumption varies from a minimum of 330,000 to a maximum of 650,000 gallons per day corresponding to a daily per capita consumption of 81 to 150 gallons respectively. Storage is provided in an elevated steel tank about 150 feet high having a capacity of some 200,000 gallons. In addition to the filtration the water is normally sterilized by means of liquid chlorine applied through a Wallace and Tiernan manually controlled solution type chlorinator. In general the details of the waterworks system remain as described in the previous report.

With further reference to the operation of the purification plant treating the public water supply it was observed at the time of the inspection that several of the baffles in the sedimentation basin had been displaced. These should be erected again in order to prevent any cross currents and inadequate mixing and coagulation. The operator stated that normally the amount of alum used varied from 40 to 60 pounds per day depending upon the physical character of the raw water. No alum, however, was being used, at the time of the inspection as the operator stated they had only a very small amount on hand and the character of the water was such that in his opinion the alum was not necessary. It appears desirable that the use of the alum be made continuous and that it be applied at the rate of at least ½ grain per gallon at times when the raw water is relatively clear which rate should be increased at times of heavy turbidity in an amount sufficient to provide a suitable floc, and the removal of turbidity in order to deliver a relatively clear water at the end of the sedimentation period. The company should also clean the coagulation basin at least once a year. It was stated that it had been cleaned about one year ago.

Normally the supply is sterilized after filtration by applying liquid chlorine to the water at a rate of approximately 2 pounds per day. With the estimated rates of consumption of 430,000 gallons per day, this is equal to a rate of application of approximately 0.5 parts per million. For this purpose two Wallace & Tiernan solution type chlorinators are provided in order that a spare chlorinator may be available for emergency use and lessen the likelihood of any interruption in the application of chlorine. At the time of the inspection, however, no chlorine was being applied to the water and our engineer was informed by the operator that the last tank of chlorine had been emptied that morning and the operation of the chlorination plant shut down.

From the records of the water company it is estimated that the total pumpage from January 1 to October 25, 1921, amounted to some 126,000,000 gallons during which time approximately 300 pounds of chlorine were applied. This corresponds to an average rate of application of 0.28 parts per million. This would appear to verify records giving the daily rate of application of chlorine varying from 1 to 2 pounds per day throughout the above period. While it is apparent from the above data that the water company had been continuously applying chlorine throughout the year until the date of the inspection, it is nevertheless, regrettable that there would be any interruption in service even after the company had gone to the expense of purchasing a duplicate chlorinator in order to minimize the danger of any such interruption. The company should not allow the supply of chlorine to become depleted to such an extent before ordering another cylinder. In fact, a good policy would be to always have one full cylinder on hand.

From the record of the amount of alum purchased and the total pumpage, it would appear that alum has been applied at an average rate of approximately 0.4 grains per gallon. Based upon the estimated consumption given above the maximum rate of filtration is approximately 70,000,000 gallons per acre per day.

As noted above, the intake is located in the Seneca river at a point some 3 miles from the outlet of Seneca lake and some 2½ miles below the point where the old canal enters the river. The city of Geneva discharges the sewage of the city untreated into Seneca lake through 3 main outfalls known as the Marsh creek, Castle creek and Mile Point sewers, at points from 1 to 1½ miles from the outlet of the lake. These sewers empty into the lake. The Marsh creek sewer is a 30-inch vitrified tile sewer provided with a cast iron outfall discharging into the lake in some 6 to 10 feet of water about 150 feet from shore. There are said to be some 5,000 people served by this sewer. The Castle creek sewer is also a 30-inch sewer discharging into the lake in some 20 or 25 feet of water at a point about 700 feet from shore. There are said to be some 8,000 or 10,000 people connected to this sewer. The Mile Point sewer is a 15-inch or 18-inch sewer discharging into the lake some 400 feet from shore in 15 feet of water. It is stated that there are approximately 1,000 people served by this sewer.

From the authorities in charge of the Geneva waterworks it was learned that the daily per capita water consumption is approximately 81 gallons in addition to which there is contributed to the sewers the flow from flush tanks amounting to a total of some 35,000,000 gallons per year plus the natural infiltration in the sewers. The sewage of the city being discharged into the lake at the opposite side of the northern end of the lake from the outlet, it would appear that by the process of sedimentation and bio-chemical action, the sewage is fairly well purified before reaching the outlet of the lake in the Seneca river except under unfavorable wind and weather conditions when some pollution from the sewers would in all probability, be carried into the mouth of the Seneca river and thence to the point of intake of the Waterloo Water Company. For this reason it is important that the utmost care should be taken to insure the continuous, careful and efficient operation of the purification plant in order that the water supply furnished the citizens of Waterloo may be of a safe sanitary quality at all times.

The old canal originally extended from the lake near the city of Geneva to the present Seneca river at a point about ¼ mile from the lake paralleling the northern shore of the lake. Since the installation of the new Barge canal system, however, this canal has been practically abandoned. The wastes from the Empire Coke and Gas Company plant near Geneva are discharged into the old canal and it has been alleged that the objectionable tastes and odors in the water have been due in part at least to the presence of these wastes in the canal which, under certain wind conditions, are carried into the Seneca river and thence to the waterworks intake.

At the time of the inspection the following information on the operation of the gas company plant was obtained: The plant is now producing 1,600,000 to 1,700,000 cubic feet of illuminating gas daily which is pumped from the plant through a force main at a pressure of 35 pounds per squar inch to the surrounding cities and villages supplied by the company. Th water supply for the plant is taken from the Barge canal and pumped b a new electrically operated pump having a rated capacity of 1,000 gallon per minute which is said, however, to be throttled down to deliver approximately 700 gallons per minute and is operating 24 hours each day.

The wastes from the ammonia condenser, light oil building and scrubbe for the blue gas all pass through a treatment plant consisting of two settlin tanks some 80 feet in length by 10 feet in width and 5 feet in depth belo the flow line. These tanks are filled with coke through which the waste are passed. One tank is used while the other is being cleaned and th coke replaced. At the time of the inspection the north tank was out o service and the coke appeared to have been recently replaced. The sout tank was delivering an effluent that was free from oil although it had dark color. The amount of wastes being discharged here was estimated a some 600 gallons per minute at the time of the inspection.

The remaining wastes from the plant consist of surface drainage, quenching water and effluent of settling tank and strainer treating the domesti sewage. It was stated that some 32 charges of coke are quenched per 2 hours instead of a maximum said to be as high as 50 charges per 24 hour in the past. On the average some 2,000 gallons of water are used in quenching each charge of coke. This amounts to an average of some 45 gallon per minute and, together with the 600 gallons per minute, passed through the treatment plant mentioned above, equals nearly 700 gallons per minute the total amount of water pumped as estimated. It was learned that th oil from the two oil recovery tanks is removed every day and placed i barrels.

At the time of the inspection the points of discharge of the wastes fro the plant into the old canal were inspected, the physical character of th effluent noted and samples collected and sent to the Division of Laboratorie and Research for analyses.

At the time of the inspection the wastes being discharged from outle No. 1, shown on the attached map, consisting of the surface drainage quenching waters and effluent from the septic tanks treating the domesti sewage, were found to be somewhat warm to the touch and to have considerable color although no large amount of solids in suspension wer observed. No distinct odor was observed.

The wastes being discharged from the outlet indicated as No. 2 on th attached map, being the effluent from the treatment plant treating th wastes from the ammonia condensers and light oil building, were observe to be very dark colored, fairly warm, to have a tarry odor and a sligh amount of oil was visible. From time to time a small amount of filamentou aquatic growths was observed to pass down the stream.

The wastes from the submerged vitrified sewer outlet, 75 feet west o outlet No. 1, were observed and had a tarry odor with some spots of oi rising to the surface and a very dark orange color. The amount o wastes flowing from this outlet was relatively small and it was stated tha this consisted of an abandoned waterworks intake pipe.

As stated above, the old canal runs from the city of Geneva at the northwesterly end of Seneca lake to the present Barge canal near the northeasterly end of Seneca lake. The amount of flow depends largely upo the direction of the wind, a west or southwest wind tending to cause th above mentioned wastes to be discharged into the barge canal. It is state both by members of the water company and by the health officer and business men's representatives that the odors and tastes in the water have i the past been intermittent and more noticeable when the wind was in th west or southwest which would tend to corroborate the above and indicat that there is some connection between the disagreeable tastes and odors i the water supply and the presence of wastes being dischargd from the cok plant. At the time of the inspection deposits of oil were observed alon the shore at the outlet of the old canal near the point where it emptie into the Barge canal, giving every indication that at certain times o unfavorable wind and weather conditions together with the probable inefficient operation of the disposal works treating the wastes of the coke plant, there is a considerable amount of oil and coal tar wastes being carried to the point of intake by the more positive and swifter current in the river. At the time of the inspection and collections of samples the wind was blowing from the north and there appeared to be little or no wastes reaching the Seneca river from the old Seneca canal.

The possibility, however, of the production of objectionable tastes and odors from the discharge into the canal of wastes from the plant of the Empire Gas and Coke Company should be given serious consideration. The occurrence of objectionable tastes and odors has been found in other places to have been due to the discharge of coal tar wastes into waters used as sources of public water supplies, especially in cases where the supplies have been treated with chlorine. The chlorine added to waters containing such wastes appears to form a compound which has a carbolic-like taste and odor. The most noticeable examples of this have occurred in the cities of Milwaukee, Toronto and Cleveland. From such observations as it was possible to make at the time of the recent inspection at Waterloo, however, it cannot be definitely stated as to what extent the tastes and odors which seem to occur occasionally in the Waterloo supply are due to the discharge into the canal of wastes from the Empire Gas and Coke Company's plant.

It will be necessary for this Department to make further investigation before this question can be definitely determined. In this connection the village authorities and the water company could aid us considerably in making daily observations of direction and velocity of winds in order to determine the direction and velocity of the wind at times when these objectionable tastes and odors occur.

There are two small surface water streams entering the river above the present intake and below the outlet of the old Seneca canal near the lake. One is known as Black creek and the other as Kendig creek and both drain a somewhat sparsely populated and relatively level watershed. These streams are subject to pollution from not alone the residents on the watersheds but also to surface wash from the highways and cultivated fields and to accidental, incidental or wilful pollution from persons crossing the watershed area. In view, however, of the fact that the water company has a treatment plant which, if continuously and properly operated, should produce a water of a safe sanitary quality, it does not appear desirable to extend the intake above the point of outlet of the two above mentioned streams.

At the time of the inspection the Business Men's Association furnished the Department with a report made and results of bacteriological examination of samples collected by the North Public Health Bureau of 30 Church street, New York city. No statement is made in the report as to the period which elapsed between the time of collection of sample and the plating, and for this reason we cannot draw any definite conclusion as to the significance of the results of the total counts. From the results of lactose broth fermentation, furthermore, no great dependence can be given due to the fact that they constitute presumptive tests only and have not been confirmed, which procedure the experience of the Department has shown to be necessary, especially with a chlorinated water, as some gas producing forms of bacteria are not removed in the sterilization by means of liquid chlorine while organisms inhabiting the intestinal tract of man and animal are effectively removed. In the report it is stated that the "offensive tastes and odors observed at taps Nos. 15, 17 and 18 are not characteristic of chlorine but are due to some other substance in the water either factory wastes or organic matter, due undoubtedly to pollution which is unaffected by chlorine." As pointed out above, however, this is not always true, as in several instances very offensive tastes and odors have been caused by the presence of coal tar wastes containing phenol in the chlorinated water even when very greatly diluted.

In a report on the supply dated December 9, 1921, it was recommended:

1. That the water company carry out the previous recommendations of this Department regarding the continuous and careful operation of the purification plant with special reference to the application of a sufficient

* Liquefied.

amount of alum and chlorine to insure that a water of safe and satisfactory sanitary quality will at all times be delivered to the consumers in the village.

2. That in this respect the water company maintain at all times sufficient supply of both alum and chlorine in order that there may be no interruption of the application of alum and chlorine as was experienced at the time of the recent inspection.

3. That this Department make further observations and studies in order to determine the cause for the objectionable tastes and odors that occur at intermittent periods.

4. That both the water company and the village officials cooperate in making daily observations and records of the wind and weather conditions, together with records of the nature of the tastes and odors observed and the velocity and direction of the wind when such tastes and odors occur in their public water supply in order that this information may be of assistance to the Department in determining the cause or source of the objectionable tastes and odors.

5. That the water company should make daily starch iodide tests for the presence of excess chlorine in their public water supply in accordance with the directions attached to this report, in order that a sufficient amount of chlorine may be applied at all times to insure the effective sterilization of the supply.

6. That the water company make frequent chemical and bacteriological analyses of the supply, in order to determine the proper amount of both alum and chlorine to be applied to obtain a water that shall be both of a safe and satisfactory sanitary quality and of a good physical quality.

WATERTOWN

A reinspection of the public water supply of the city of Watertown, Jefferson county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on April 13, 1921. Previous inspections of the supply were made by this Division in 1909, 1914 and 1918, the reports on which are published in the 30th, 36th and 39th Annual Reports of the Department respectively.

Watertown has a present population of about 30,000, practically all of whom are served by the public water supply. The waterworks are owned and operated by the municipality under the control of the department of water, light and power, of which Mr. J. W. Ackerman is superintendent. The water supply is derived from the Black river, about 2 miles east of the city, and is subjected to aeration, coagulation and filtration through gravity rapid sand filters and chlorination before being pumped directly into the mains.

Black river above the intake has a watershed area of 975 square miles, on which there is a population of about 30,000, about 20 per cent of whom discharge untreated sewage into the river. The river also receives considerable pollution from wastes of pulp mills along the stream.

Since the last inspection in 1918 a number of changes in the equipment and operation of the filtration plant have been made. Additional filtration units have been installed to care for the increased consumption, although by the policy of metering the consumption has already been considerably reduced. The river channel is now permanently used as a coagulating basin, except at times of high water. Liquid chlorination apparatus, installed in duplicate, has replaced the hypochlorite method of sterilization. Changes have also been made in the pumping equipment. No action has been taken by the city in regard to the question of a revision of the rules and regulations for the protection of the supply. The city authorities are contemplating the enactment of an ordinance in regard to the maintenance of cross connections of auxiliary supplies with the public water supply.

In a report dated April 28, 1921, on an inspection of the supply, the following recommendations were made:

1. That consideration be given to the revision of the rules and regulations.
2. That all cross connections with private supplies be provided with double check valves, properly installed and accessibly located.
3. That scales be provided under the cylinders for weighing the chlorine.
4. That the present careful oversight of the operation of the purification plants be maintained.

WATERVLIET

An investigation of the public water supply of the city of Watervliet was made by Mr. Earl Devendorf, assistant engineer in this Department, on May 6, 1921. Previous investigations of this supply were made in 1918 and 1919 and reports thereon published in the Annual Reports of the State Department of Health for those years.

Watervliet is a city of some 17,000 inhabitants, located in the northern part of Albany county. The city is served with a public sewer system, the sewage from which is discharged, without treatment, into the Hudson river. The water supply is obtained from an impounding reservoir constructed on the Normanskill creek some 14 miles west of the city. The water is pumped to a raw water reservoir about ½ mile west of the city and from the reservoir flows by gravity through a gravity mechanical filter plant to the distributing system in the city. The water supply is owned by the city and is operated along with the other city departments under Mr. H. E. Gabriels, general manager, and Mr. N. J. Normile, chemist in charge of the filter plant. The average daily consumption for 1920 was 3,200,000 gallons per day, of which 561,300 gallons per day were used for industrial purposes.

In the 1918 report it was recommended that the city authorities curtail the water consumption by the installation of meters, operate the reservoir and pumping station at French Mills so as to preclude any serious depletion of the supply and operate the purification plant with the greatest care and efficiency, employing a resident chemist. It was further recommended that a second pipe line be installed from the filter plant to the general distribution system and that the Arsenal authorities separate their water supply systems at the earliest possible date.

At the time of the recent inspection it was learned that the city authorities have installed additional meters and are contemplating the installation of as many more meters as the finances of the water department will permit. The city authorities have installed an additional electrically operated pump at the pumping station at French Mills to be used for pumping water to the raw water storage reservoir. This unit is of such a capacity that when operated with one of the hydraulically operated pumps it will supply sufficient amount of water for the city's needs. The authorities at the Arsenal have separated their two systems of water. To date the city has not installed a second pipe line leading from the filter plant to the general distribution system.

On May 19, 1920, a serious break occurred in the wood stave pipe leading from French's Hollow to the raw water storage reservoir. The work of repair on this pipe line was not completed until June 15, 1920, when the filter plant was again operated. During this interval water was supplied to the city by pumping from the Hudson river through the pumping station located at the Arsenal. Again on June 18, 1920, a small break in the pipe line occurred. Pumping was started again on June 24 to fill the storage reservoir and the filter plant again started on August 1st. During this period also water was furnished to the city by pumping from the Hudson river through the Arsenal pumping station. The Hudson river water was chlorinated, using approximately 2 parts per million before being delivered to the distribution system for consumption.

At the filter plant 7 of the 10 filter units were in operation at the time of the inspection. Alum was being applied to the raw water approximately at the rate of 1¼ grains per gallon. The aerators at the filter plant were in operation, having been started about April 1st. From an examination of the Venturi meter charts the quantity of water filtered varies from a maximum of 4½ million gallons per day to a minimum of 2 million gallons, corresponding to rates of 116,000,000 to 52,000,000 gallons per acre per day.

Chlorine is applied through a Wallace & Tiernan dry feed apparatus and was being operated under manual control. An automatic control was installed at the time the plant was constructed but some trouble had been experienced in the operation of the manual control apparatus, due to the liquid in the manometer being thrown out when the flow of water from the filter plant was changed by the opening or closing of a valve on one of the filter units. It would appear desirable to have a representative of the Builders Iron Foundry examine the installation in order to determine the cause and overcome the trouble, so that the amount of chlorine applied to the water may be regulated in proportion to the amount of water being filtered as provided for by the original design and installation. Scales are provided for weighing the cylinder and checking the operation of the chlorine apparatus. Chlorine is being applied at the average rate of approximately .36 parts per million.

The authorities in charge of the public water supply, since the time of the break in the main trunk line leading to the raw water storage reservoir from French Mills pumping station, have employed a patrolman who daily inspects this line. By this means any small leaks which may occur are discovered and repaired immediately. In the spring of 1919 the city authorities engaged the Pitometer Company to make a survey of the water distribution system in order to discover and eliminate any leaks. This survey indicated that the greatest water waste was in the house services and in the under registering of the industrial meters.

In a report upon the supply dated May 20, 1921, it was recommended:

1. That the city authorities continue their careful operation of the filter plant and the pumping station at French Mills in order that a continuous supply of water of good sanitary quality may be furnished at all times.
2. That the city authorities continue to curtail as much as possible the waste of water by discovering and eliminating leaks and by installing meters.
3. That the city authorities install, as previously recommended, a second pipe line from the filter plant to the city distribution system or install a by-pass line at the railroad crossing, provided with valves.

WATKINS

A reinspection of the public water supply of the village of Watkins was made by Mr. W. J. Erickson, sanitary inspector, on April 12, 1921. Previous inspections of this supply were made in 1913, 1915 and 1917, the reports upon which are published in the Annual Reports of this Department for the respective years.

Watkins, which is a village of about 2,800, is located in Schuyler county at the southern end of Seneca lake, 22 miles north of Elmira. The Watkins Glen station on the Pennsylvania division of the New York Central is about 2 miles from the village which may be reached by a bus line. Practically the entire population is served by the public water supply which is owned by the village and operated under the direction of the board of water commissioners of which Mr. C. M. Cole is president and Mr. Charles E. Dennis is superintendent. The supply is derived from Seneca lake. After sterilization with liquid chlorine it is pumped to 2 storage reservoirs serving the high and low levels of the village. From these reservoirs the water flows by gravity through the distribution system. The chlorination plant is located in a small brick room adjacent to the power plant. The apparatus which is of the solution feed type is in duplicate so that should one be out of order it would not be necessary to stop chlorinating while it is being repaired. One of the apparatus had been shipped to the manufacturers for repairs at the time of the inspection. The chlorine is applied to the suction line of the pumps. At the time of the inspection the chlorine was applied at such a rate as to require 18 seconds for each pulsation or approximately 1.2 pounds per day. As one pump only was in operation at that time this corresponds to about 0.29 parts per million of chlorine. When two pumps are in operation the rate of application is regulated so as to apply the chlorine at about the same rate. At times of heavy rains and when the condition of the lake currents warrant it, the rate of application of chlorine is increased so as to yield a safe water at all times. Scales are provided for checking the weight of the chlorine used. At times of heavy runoff the lake, especially near the eastern shore becomes very turbid. This turbidity is carried by eddy currents back along the west shore and past the intake. It would seem advisable in order to remove this turbiditty that the supply be subjected to some modern method of filtration.

Watkins Salt company plant has a cross connection between their sprinkler system and the village system. It is said that the village supply is protected by two check valves. Whether these are single or double check valves, could not be ascertained as they are covered and the exact location not definitely known although it was said that they were located between the main and the first hydrant on the company line. The Salt company obtains their supply by pumping from the lake. It was stated that during the summer months the village water is used in the sprinkler system. In case of fire and during the winter, however, the brine water is pumped into the system. It was said that only brine is ever pumped into the system. No other cross connection exists between the village mains and the company supply.

At the time of the 1917 inspection it was pointed out that the rate of applying the chlorine was not varied with the rate of pumping, that inadequate records were kept regarding the operation of the plant and that the results of analyses show inefficient sterilization. It was accordingly recommended that plans for the treatment of sewage of the village of Watkins be submitted to the Department for approval, that consideration be given to installing a filtration plant, that the rate of applying the chlorine be regulated so as to apply not less than .25 parts per million at all times, that the operation of the plant be checked by the weighing scales and that complete records of the operation of the plant be kept.

From the recent inspection it appears that the sterilization plant is better regulated and that our recommendations in this respect have been acted upon. However, no action has been taken by the village toward the installation of a filtration plant nor have plans for sewage disposal been submitted.

In a report upon the supply dated April 22, 1921, it was recommended:

1. That the village continue to operate the chlorine plant efficiently at all times, keeping records showing the amount of chlorine applied as indicated by the chlorine meter and also by the scales, the time the new cylinders are connected, the amount of water pumped and any troubles or difficulties in connection with the operation of the plant.
2. That plans for the treatment of the sewage of the village be submitted to this Department for approval.
3. That consideration be given to the installation of a modern filtration plant.

WAYLAND

A reinspection of the public water supply of the village of Wayland was made by Mr. W. J. Erickson, sanitary inspector, on April 13, 1921.

Previous inspections of this supply were made in 1909 and 1917, the reports upon which are published in the annual reports of this Department for the respective years.

Wayland, which is a village with a population of about 1,700, is located in the northwestern part of Steuben county about 40 miles south of Rochester. There is no sewer system in the village. The water supply is owned by the village and operated under the direction of the board of trustees. It is derived from a well located in the northwestern part of the village from which the water is pumped through the distribution system into a storage reservoir located on a hill just northeast of the village. The consumption averages about 100,000 gallons per day.

The well from which the supply is obtained is located in the northwestern corner of the village near the Erie railroad tracks. It is 25 feet deep and 10 feet in diameter, It is curbed with fire brick laid in cement mortar and covered. In the bottom of this well 5 pipes are driven to depths of from 8 to 15 feet. The water rises to within 15 feet of the ground surface. The well and driven pipes extend through 10 feet of gravel, 5 feet of clay, into water bearing gravel. The sanitary conditions surrounding the well are the same as described in the previous report. A cesspool is located about 95 feet southwest of the well and two privies about 200 feet in the same direction. The electric light plant is about 20 feet and a feed mill about 50 feet distant. Across the tracks to the northeast is a silk mill which employs, under ordinary conditions, about 150, although fewer are being employed at present. The sewage from the mill is discharged into 3 settling tanks located about 250, 300 and 400 feet from the well. Although the well is protected from surface wash by an embankment around the curb which diverts it, the disposal of sewage from a comparatively densely populated area, in cesspools and privies undoubtedly contaminates the ground water in the vicinity, and this contamination may under certain hydrostatic conditions find its way into the supply, either by passing through the wall of the well or through openings in the clay strata into the ground waters tributary to the well. As a method of protecting the supply from contamination and improving conditions in general a comprehensive sewer system to care for the house wastes might be constructed. The sections of the system within 100 feet of the well should be laid with cast-iron pipes with leaded joints. The development of a new supply from a source remote from the built-up section of the village where the village authorities might control a considerable area in the vicinity and effectively protect the water would, of course, be more desirable.

At the time of the previous inspection it was pointed out that although past analyses failed to indicate any active contamination, the water supply is derived from a well which is unsatisfactorily located. It was accordingly recommended that the insanitary conditions be improved by constructing a sanitary sewer system, that pending the completion of the sewer system all privies and cesspools within 500 feet be provided with tight removable containers, the contents of which are to be disposed of at regular intervals, that should any active contamination be found steps be taken to remove the same, or should this prove impracticable to sterilize the supply; or if these methods should fail, a new supply, free from all sources of pollution be developed. From the recent inspection it appears that none of these recommendations have been carried out.

In a report upon the supply dated April 30, 1921, it was recommended:

1. That the village authorities consider the development of a new water supply derived from a source so located and protected as to be free from all possibility of contamination.

2. That pending the development of such a supply the present well be protected as far as possible from contamination by making all the cesspools in the vicinity watertight, providing all the privies with removable, watertight containers and maintaining the cesspools and privies in satisfactory sanitary condition, or constructing a comprehensive sewer system and abandoning all the privies and cesspools in the vicinity.

WAYLAND (Delaware, Lackawanna and Western Railroad)

An inspection of the water supply furnished to the Delaware, Lackawanna and Western railroad by the Gunlack Chair company was made by Mr. W. J. Erickson, sanitary inspector, on April 13, 1921.

The water supply is owned and controlled by the Gunlack Chair Company, for which Mr. W. H. Gunlack is manager. The water supply is derived from a well located on property adjacent to the chair works about a mile south of the village and adjacent to the Delaware, Lackawanna and Western railroad tracks. Besides supplying the railroad with water at the station it also supplies drinking water and water for the sprinkling system in the mill. The well is drilled, 8 inches in diameter and 70 feet deep, extending through about 45 feet of gravel and 25 feet of rock. The well is adequately protected from surface wash. A sewer passes within about 75 feet of the well and empties its contents into a cesspool about 200 feet from the well. There appeared to be little opportunity for contamination from the cesspool, although the possibility of leakage from the sewer seems a potential source of pollution.

In a report dated May 2, 1921, on an inspection of the supply, the following recommendations were made:

1. That the premises be kept in a neat and sanitary condition at all times and that all possible precautions be taken to prevent pollution of the soil in the vicinity.
2. That the owners of the supply consider the development of a new supply of unquestionable purity and from a source more satisfactorily located.

WELLS BRIDGE

A reinspection of the public water supply of the village of Wells Bridge, Otsego county, N. Y., was made by Mr. N. H. Baier, sanitary inspector in this Department, on March 2, 1921.

A previous inspection of the supply was made by this Division in the year 1917, the report upon which is published on page 569 of the Annual Report of this Department for that year.

Wells Bridge is located on the Susquehanna river in the southeastern corner of the town of Unadilla, 13 miles southwest of the city of Oneonta. The present population is 125, of whom 95 per cent are served by the public supply. The waterworks, called the Wells Bridge Waterworks Company, are owned and operated by Mr. Seymour L. Root. The water is derived from a spring, located on a hillside a mile northeast of the village, from which it flows by gravity through a 1-inch lead pipe to a distributing reservoir situated on a knoll some 600 feet north of the village. There was no method of estimating the amount of water consumed in the village. The village has no sewerage system, about three-fourths of the population sewering directly into the Susquehanna river while the remainder have cesspools.

The spring is developed by a basin of masonry construction 4 feet in diameter by 2 feet deep covered with loose boards. The apparent watershed, which is remote from any habitation, is about 0.15 of a square mile of forested land having a hard pan subsoil. The construction of the basin is such that both surface wash and chance or wilful contamination may reach the supply. To eliminate such possibility the wall of the basin should be extended about a foot above the surrounding ground surface and a more substantial covering provided. Inspections of the watershed are made a few times each year.

The reservoir is of concrete, circular in form and covered with a conical wooden roof.

The sidewalls extends about a foot above the surface of the surrounding ground. The reservoir is cleaned once a year and the mains are flushed a few times yearly. The land around the reservoir is enclosed by a fence.

In our previous report it was recommended that steps should be taken to more satisfactorily develop the spring supply by constructing a masonry or concrete curb around the spring, which would extend at least 1 foot above the surface of the ground and provide the basin thus formed with a tight cover and that in order to avoid the necessity for the use of the auxiliary well an additional spring, satisfactorily located and free from possibilities from contamination, should be developed and connected with the present reservoir.

From our recent investigation it appears that conditions remain practically the same as at the time of our previous inspection. The auxiliary well, the use of which has been resorted to on two occasions, has not been in use for some years, since the present supply has proven adequate to supply the needs of the village.

In a report upon the supply dated March 22, 1921, it was recommended:

1. That the spring basin be adequately protected from surface wash by extending the walls of the basin about a foot above the surface of the ground.
2. That a more substantial cover be provided for the basin to avoid chance or wilful contamination.

WESTERN NEW YORK WATER CO.

A reinspection of the public water supply furnished by the Western New York Water company to the city of Lackawanna and a number of villages, and towns in Erie county was made on December 9 and 10, 1920, by Mr. Albert I. Howd, assistant engineer in this Department, accompanied by Mr. H. F. Huy, General Manager of the Western New York Water Company. Previous investigations of this supply have been made by the Department in 1912 and 1915.

The water supply of the Western New York Water company is obtained from Lake Erie, the intake being located 6,000 feet off shore at Woodlawn beach, which is about 2½ miles south of the southern boundary of the city of Buffalo. The water flows by gravity through the intake pipes to the suction well of the pumping station at Woodlawn, where it is chlorinated and pumped into the distribution system, the surplus over consumption flowing into an open reservoir in the town of East Hamburg. A second pumping station and reservoir are located at Depew. The water is pumped from the Depew reservoir into a high service system. Depew and Lancaster and all mains north of the New York Central railroad tracks are on the high service system.

The Western New York Water company sells water wholesale to a number of villages which own and maintain their own distribution systems. The villages so supplied are Blasdell, Lancaster and Kenmore and about 50 per cent of the town of Tonawanda. The company owns the distribution system and furnishes water to the following places: The city of Lackawanna, villages of Depew and Sloan, and the whole or portions of the towns of Alden, Amherst, Cheektowaga, East Hamburg, Hamburg, Lancaster, West Seneca and Tonawanda. The total population served with water by the Western New York Water Company is about 50,000. The water consumption is about 30 gallons per capita. In addition to the water furnished for domestic consumption water is supplied to a number of railroads and some 60 manufacturing plants in the several villages and towns mentioned above. The average total daily water consumption is about 9,000,000 gallons. At the time of the inspection the Venturi meters at the Woodlawn pumping station indicated 9,960,000 gallons as the daily rate of pumpage. The records at the pumping station showed that for the period between November 19 and December 8, 1920, the average amount of water pumped daily was 9,623,000 gallons. The minimum amount of water pumped on any day during this period was 8,380,000 gallons on November 25, and the maximum amount was 10,813,000 gallons on November 27.

The intake of the water supply consists of two concrete cribs located in Lake Erie about 6,000 feet off shore and at a depth of approximately 24 feet below the water surface. The cribs are 8 feet square and the tops of them are covered with bar screens having 1 inch openings. The water collected by these cribs flows into two cast-iron pipe lines, 20 inches and 30 inches in diameter, which unite some distance off shore. From this point a 30-inch pipe is laid to the suction well in the pumping station. The suction well is 10 feet wide, 40 feet long, and 26 feet deep. One-quarter-inch mesh screens are provided in the well to further protect the pumps.

The water is treated with liquid chlorine in the suction well at the pumping station. The report on the investigation made by this Department in 1912 pointed out that the water supply was somewhat polluted at more or less infrequent intervals by the sewage which is discharged into the lake from nearby thickly populated sections and recommended that a sterilization plant be maintained at the pumping station for the treatment of the whole supply. The Western New York Water Company accordingly installed an apparatus manufactured by the Electro-Bleaching Gas Company for the sterilization of the supply with liquid chlorine in December, 1913. This apparatus was replaced in April, 1920, by a manual control, solution feed type of chlorinator manufactured by Wallace & Tiernan. Chlorine is generally applied at the uniform rate of 2 pounds per million gallons. If the turbidity of the water reaches over 100 parts per million. it was stated that the amount of chlorine is increased to 2½ pounds per million gallons. At the time of the inspection chlorine was being applied to the water at the rate of about 19 pounds per 24 hours. Since the rate of pumpage was 9,960,000 gallons per 24 hours, the amount of chlorine being applied was equivalent to 0.23 parts per million. For the 20 days previous to the date of the inspection the average amount of liquid chlorine applied to the water was 0.20 parts per million. On 8 of the 20 days the amount of chlorine applied dropped below 0.20 parts per million, the minimum amount being 0.14 parts per million on December 5 and the maximum amount 0.25 p. p. m. on December 2.

The chlorine is applied in the corner of the suction well to one side of the entrance of the intake pipe. It seems possible that under certain conditions the chlorine might not be uniformly applied to the water. For instance having in operation the first pump, the suction of which is near the point of application of the chlorine, and the third pump, the suction of which is at the other end of the suction well, it seems possible that the larger part of the chlorine solution might go to one pump. If both pumps discharge into the same main the chlorine might become more uniformly mixed with the water, but if the pumps discharge into the two separate mains from the pumping station, it seems possible that some consumers might receive insufficiently chlorinated water. It would seem, therefore, that the chlorine might better be applied directly into the intake pipe in the suction well, or at some other point more satisfactory than the present one. Duplicate parts of the chlorination apparatus are kept on hand and the old Electro-Bleaching Gas Company's apparatus is available for use if necessary. Scales are provided under the chlorine cylinders for checking up the amount of chlorine used and the tolidin test is made daily for excess chlorine. A visit at the pumping station by an engineer of the Department on January 8, 1921, showed that the tolidin standards, which are kept in 100 cc. Nessler tubes, had evaporated to about one-half their original volume and hence were in an unsatisfactory condition. They should, therefore, be renewed. There were 700 to 800 pounds of liquid chlorine or about 40 days' supply on hand at the time of the inspection.

The water is pumped from the building through a 16-inch and a 24-inch pipe line directly into the mains, the surplus flowing through a 24-inch pipe to the Windom reservoir in the town of East Hamburg, about 4½ miles directly east of the Woodlawn pumping station. This reservoir is of earth embankment construction and is concrete lined. It is 500 feet in diameter, 13 feet deep, and has a capacity of 10 million gallons or about 1 day's supply. There is one inlet and outlet pipe which enters the bottom of the reservoir.

The reservoir is constructed above the surrounding ground and is, therefore, not subject to surface wash. The reservoir is surrounded by an iron fence.

The Depew reservoir is constructed of concrete with an earth embankment. The reservoir is 200 feet square and 13 feet deep, and has a capacity of 3½ million gallons. The reservoir has a 16-inch inlet pipe at bottom of reservoir and four 16-inch screened outlet pipes. The reservoir is constructed above the surface of the surrounding ground and is surrounded by a fence.

The waters along the southern and eastern shore of Lake Erie are subject to considerable pollution from sewage from a number of cities and villages. Some of the more important of these places in New York State include Westfield (3,500), the sewage from which is discharged through Chautauqua creek into Lake Erie; the sewage from Fredonia (5,500) is discharged into Canadaway creek before it enters the lake; the city of Dunkirk (18,000), empties its sewage through numerous outlets into Lake Erie; the sewage from Silver Creek (3,200) and Hamburg (3,000) is also discharged into creeks tributary to Lake Erie. The waters in the vicinity of the intake of the Western New York Water Company are subject to direct or indirect pollution from Athol Springs, Bay View, Woodlawn Beach, Blasdell and Lackawanna. Smoke creek, considerably polluted by the sewage from the city of Lackawanna which has a population of about 16,000 and by industrial wastes from manufacturing plants, empties into Lake Erie about 1 mile below Woodlawn Beach. Buffalo creek, heavily polluted by sewage from the city of Buffalo discharges into Buffalo harbor several miles below Woodlawn beach. The last two cases mentioned are probably the most important, since they discharge enormous quantities of polluting matter into Lake Erie within a relatively short distance from the intake of the Western New York Water Company's water supply.

It was learned at the time of the inspection that the Western New York Water Company has considered filtration of this water supply. The space in the pumping station now occupied by the emergency steam pumping equipment has been considered suitable for the location of rapid sand filters. Although no definite plans have been made, according to the statements of the water company, any changes or improvements made at the pumping station are made so that they would not interfere with and might be incorporated in a filtration plant.

In a report upon the supply dated January 28, 1921, it was recommended:

1. That the Western New York Water Company continue their careful supervision of the water supply furnished to the city of Lackawanna and other villages.
2. That the tolidin standards be renewed or the starch iodide test substituted for the tolidin test and that frequent tests be made to determine the excess of chlorine in the treated water.
3. That the chlorination apparatus be carefully operated and controlled and sufficient chlorine applied in a proper manner and at all times to show a slight excess in the treated water by the tolidin or starch iodide test and properly sterilize the water.
4. That the Western New York Water Company consider the immediate installation and operation of a modern filtration plant for the treatment of their water supply derived from Lake Erie, so that a water of satisfactory sanitary quality may be furnished to the consumers at all times.

WHITEHALL

An inspection of the Whitehall public water supply was made by Mr. Earl Devendorf on June 3, 1921.

Whitehall is located in Washington county, 78 miles north of Albany. The population is 4,700, all of which is served with the public water supply. The waterworks are in charge of a board of water commissioners of which Mr. James Sullivan is president, Mr. E. H. Syring, superintendent, and Mr. M. G. Therrien, engineer. The source of supply is the Mettawee river, and the con-

ı amounts to approximately 1,100,000 gallons per day and is delivered
ping directly into the village main. An auxiliary upland supply is
e and is used at times when the Mettawee river is very turbid.
ply is delivered by gravity from reservoirs to the village distribution
Storage is provided by an earth embankment reservoir having
0 gallons capacity. The Mettawee river supply is sterilized by means
chlorine before being pumped into the village distribution system.

s found upon inspection that the conditions surrounding the supply
ctically the same as described in the report of July 26, 1918. With
e to the application of chlorine examination of the village records
that chlorine was being applied at an average rate of approximately
s per million.

pland supply is used without treatment but the watershed is
and uninhabited and not subject to any permanent sources of
n, although it is subject to accidental, incidental and wilful pollution
nters or visitors thereto.

hlorine content is also somewhat high indicating the presence of
n of human or animal origin. The results of the bacteriological
tion of the chlorinated water with the chlorination apparatus operat-
he rate of 13 pulses per minute, at which time, when a very faint
s obtained, showed a somewhat high total count with the absence
isms of the B. Coli type in all of the inoculations examined. With
aratus operating at 20 pulses per minute the count is low and the
ns of the B. Coli type were absent in all inoculations. The results
acteriological examination of the sample collected from a tap in the
show low total counts with the absence of organisms of the B. Coli
all of the inoculations examined, indicating that the supply was free
ive contamination and that the chlorination plant was being operated
fective manner at the time of the inspection.

memorandum upon the supply dated December 31, 1921, it was con-

. That as yet the village has not taken any definite steps for acquiring
ew supply or providing further treatment for the present supply.

. That the chlorination apparatus was being operated in an effective
nner and the supply appeared to be in a fairly satisfactory sanitary
dition at the time of the inspection.

---

dition to the above, inspections were made and detailed reports
in cases of water supply at the following places:

le Chasm, Bainbridge, Batavia (State School for the Blind), Bergen,
Falls, Brocton, Candor, Castorland, Cold Spring, Corning, Delancey,
shkill (school), Fishkill (brick yards), Gilbertsville, Groton, Hobart,
Huntington, Lawson Lake (camps), Locke, Mamakating, Milford,
n, Morris, Mt. Upton, Norfolk, Nunda, Oyster Bay (Farmade Farms),
ensselaer, Walton, Warrick (N. Y. Telephone Co. Home), and West
(camp).

TRANSMITTAL OF REPORT UPON ANALYSES OF PUBLIC WATER SUPPLIES

During 1921 some 200 letters were written to water companies and local authorities in charge of the public water supplies in which the results of the water analyses made by the Division of Laboratories and Research were transmitted. In each case the results of the analyses were carefully studied and interpreted and recommendations were made for improvements in the supplies when the analyses indicated that the supplies were not of satisfactory sanitary quality.

INVESTIGATIONS OF COMPLAINTS RELATING TO STREAM POLLUTION

INVESTIGATIONS OF COMPLAINTS RELATING TO STREAM POLLUTION

The discharge into the watercourses of this State of sewage, wastes from creameries, industrial wastes, garbage, and other refuse is the source of many complaints made each year to the Department. The substance of the complaints usually is that the stream is so polluted that very objectionable odors are created, or that cattle cannot drink the waters of the stream, or that the waters are used for bathing in the summer and ice harvesting in the winter, the pollution of which constitutes a menace to health. The complaints generally come from people directly affected by the nuisances but very often requests for assistance and advice in dealing with cases of stream pollution come from local boards of health or village officials.

In cases where conditions warrant it, a careful investigation is made of the stream and its surroundings and the source and nature of the pollution. A report is prepared describing the conditions found to exist and recommendations are made as to the remedial measures which should be taken. Copies of the report are transmitted to the local board of health, to the sanitary supervisor, to the complainants, and to the parties causing the pollution of the stream.

The reports upon a few of the more important of such cases which came before this Department during 1921 are given below and a list is also appended of all other cases.

NEW ROCHELLE

An investigation of the pollution of the tidal waters of Echo bay and vicinity at New Rochelle was made on November 17, 1920, by Mr. A. I. Howd, assistant engineer in this Department, accompanied by Mr. R. R. Cooper, sanitary inspector for the department of health of New Rochelle, and Mr. A. C. Allen, assistant engineer of the department of public works of New Rochelle.

The investigation was made as a result of complaints received at this Department. In October, 1920, a complaint was made regarding the presence of sewage during the summer in the waters near Stonebergs and the stone pier. In the spring of the same year a complaint was received in reference to objectionable conditions created in the inner arm of Echo bay by the discharge of raw sewage and garbage from house boats. The allegations of the complainants may for convenience be generally stated as follows:

1. That house boats, launches and other crafts are moored during the summer season in Echo bay near Hudson park where public bathing beaches are maintained and that the discharge of raw sewage and garbage from these boats is injurious to the health of bathers and creates conditions of nuisance.
2. That in the winter season these house boats are anchored in coves near the shore, the boats being generally aground at low tide at which time a nuisance is created from the discharge of raw sewage and garbage.

Since the present investigation was made in November it was impossible to verify the conditions complained of during the summer season. It was learned, however, that during the summer some 25 house boats and some 150 yachts and launches are moored or cruise around in Echo bay opposite Hudson park not far from the bathing beaches; and that the sewage and wastes from these boats are discharged directly into the bay.

It was, however, possible to investigate during the inspection the conditions as they existed at that time. There were found at the time 11 house boats moored in the northerly cove of Echo bay near the Stonebergs, 10 of which were occupied. The boats as a rule are provided with flush closets and sinks, the water for use in these fixtures being pumped from the bay into a tank on top of the boat. At low tide the boats generally rest on the ground and the sewage and wastes from the boats are, therefore, discharged onto the ground. At high tide the boats are floated and the sewage and wastes are, under this condition, discharged into the water. The garbage and other household wastes are thrown overboard. While no conditions of nuisance could be said to exist at the time of the inspection, it is probable that during the summer time the discharge of sewage and wastes from these and other craft would be a menace, if not a nuisance to health and might properly be regulated by the local health regulations. It is possible that the ordinance enacted by the department of health of New Rochelle on February 3, 1916, requiring that "no house boat be allowed to be moored nearer the shore than low water mark between May 1 and September 15," may, if properly enforced, partially remedy the conditions that exist during the summer season but could hardly be expected to wholly remedy these conditions. To effectively remedy these conditions it would seem necessary to further restrict the moorage and anchorage of these boats and to prohibit by proper ordinances the discharge of raw sewage and excreta from water craft generally within certain restricted areas.

A 24-inch outfall sanitary sewer serving a large section of the city of New Rochelle passes through Hudson park and extends for a distance of some 3,000 feet into Long Island sound, where it discharges 20 feet below mean sea level. The pipe line is constructed of cast-iron pipe and as far as is known it does not leak. It is quite possible that some sewage discharged from this and other outfalls is carried to bathing beaches and the waters of Echo bay by the tides and the only satisfactory means of correcting pollution from these sources would be the installation of sewage disposal plants for the treatment of this sewage.

It was pointed out in a report dated January 18, 1921, that the conditions concerning which complaints have been made might be most satisfactorily regulated by the enactment and enforcement of appropriate local ordinances, as pointed out above, supplemented by the construction of sewage disposal plants, and it was recommended that such action be taken by the local authorities. Copies of the report were sent to the local department of health of the city of New Rochelle and to the complainants.

ONEIDA

An investigation of a complaint in regard to the pollution of Oneida creek at Durhamville, Oneida county, by the discharge of sewage from the sewer system of the city of Oneida was made on July 19, 1921, by Mr. Albert I. Howd of this Division as a result of complaints to the local board of health of the town of Verona and at the request of the local health officer.

The city of Oneida is located on a relatively flat area of land in the northeastern part of Madison county. The city has a population of 10.541 according to the census of 1920, an increase of 2,224 or 26.7 per cent since 1910. Oneida creek flows along the eastern edge of the city. Durhamville is an unincorporated village having a population of 730 and is also located on Oneida creek about 1½ miles north of and below the city of Oneida.

The matter of sewerage and sewage disposal for the city of Oneida has been before this Department for some time. Plans for a comprehensive sewer system and for a sewage disposal plant for the then village of Oneida were approved by the State Board of Health on April 6, 1892. The sewer system was constructed during the fall of 1896.

As a result of a complaint an investigation was made on October 9 and 10, 1896, at which time it was found that the contract for the construction of the sewer system was nearing completion and that no provision was being made for disposal works, nor had property been secured on which to build the disposal works. It was pointed out in the report upon the investigation that the character of Oneida creek and the circumstances attending it were such that any further addition of sewage to the present amount discharged into it would be quite certain to constitute a nuisance. In 1897, 1898, 1899 and 1901 plans were approved for changes and additions to the sewer system.

The waters of Oneida creek were very low in 1908, as a result of which very objectionable conditions were created at Durhamville by the discharge of sewage from Oneida into the creek. Revised plans for sewerage were submitted for approval on October 21, 1913; were approved on November 10, 1913, and a permit issued in connection with the approval of the plans allowing the discharge of effluent from the proposed sewage disposal works. The plans provided for sewer extensions, an intercepting sewer and a sewage disposal plant consisting of a pumping station, Imhoff tanks, dosing tanks, sprinkling filters and sludge beds. Application was made to this Department on March 26, 1914, for permission to temporarily omit from construction the sprinkling filters, since the village was financially unable to construct the entire works. After careful consideration this Department gave permission to the village to temporarily defer the construction of the sprinkling filters on condition that they should be constructed and put in operation by November 1, 1915.

The present investigation disclosed the following facts: The city is provided with a system of sewers constructed on the separate plan which serves about 75 per cent or more of the city. One short section of storm water sewers empties into the separate sewers. The sewage from the system is discharged through two outfall sewers into Oneida creek. It was learned that the city has purchased a small area of land, now being used as a refuse dump, and was contemplating buying about 25 acres of land for a site for a sewage disposal plant. No active steps have been taken, however, to provide for the construction of a sewage disposal plant. The storm water sewers generally empty into a canal feeder which runs through the city.

One outfall sewer serves the section of the city north of the New York Central railroad tracks and a small area in the western part of the city south of the New York Central railroad tracks. This sewer is 24 inches in diameter. It receives about ⅜ of the total sewage flow of the city and empties into Oneida creek about 1,000 feet north of the New York Central railroad bridge. The sewer is of tile and terminates in the stream at a point near the shore. A cast-iron pipe apparently was intended to carry the sewage to midstream, but the cast-iron pipe has become upheaved so that the end is out of the water and the tile pipe has become broken near the shore so that the sewage empties through a joint in the tile into the creek. The waters of the creek were very turbid above the outfall sewer. The sewage somewhat discolored the stream. At the bend of the stream below the outlet an accumulation of scum was noticed.

The second outfall sewer is 24 inches in diameter and empties into Oneida creek a few hundred feet above the New York Central railroad bridge. The discharge of the sewer was entirely submerged. The sewage somewhat discolored the waters of the creek.

The latter sewer receives in addition to the sanitary sewage from a large portion of the city, the wastes from the Oneida factory of the New York Canners, Inc., successor to the Burt Olney Canning Company. The wastes including blanching water and wash water from floors and apparatus, are discharged through floor drains into screening manholes. These manholes are a few feet deep and are provided with metal bar screens having ½-inch 1-inch spacings and lying in a horizontal position. The wastes are d charged from the manholes through pipes directly into the city outfall sev which passes through the property of the company. The drainage from ensilage stacks is discharged into cesspools. The solid wastes from plant such as skins and other matter are dumped onto the ground a f hundred feet in the rear of the factory. The domestic sewage from t factory is also discharged into the city sewer system.

The wastes from the gas works of the city are discharged into a dit running along the foot of the New York Central railroad tracks and d charging in Oneida creek. Oily wastes were noticed in this ditch.

The complainants and members of the local board of health of the to of Verona were interviewed and the stream at Durhamville was inspec with them. Portions of the stream and particularly the rocks in the stre were covered with a grayish slime or fungus growth, giving evidence sewage pollution. A black muck about one foot deep existed at differ points on the bank and bed of the creek. Upon stirring up the bed of stream black scum and sludge quantities of oil rose to the surface, giv rise to objectionable conditions. Owing to recent rains, the creek was hig than it had been as a result of which the condition of the stream somewhat improved. It seemed evident however that under certain atm pheric conditions and at times of low water, a serious nuisance would created.

The complainants allege that the odors that arise from the stream dur the summer permeate their houses and are very obnoxious and unhealthf It is further alleged by them that vapors and gases arise from the stre which discolor and destroy paint on their houses.

The matter of providing works to treat the sewage of the city of Onei before its discharge into Oneida creek has been before this Department a the city authorities for a considerable time. The insanitary condition of creek and the necessity of providing works for treatment of the sewage l been brought to the attention of the city authorities on a number of occasi but up to the time of the present inspection no definite action has b taken by them. With a limit of bonded indebtedness of about $550,000 a having at present an indebtedness of only about $300,000, the city shou be in a position to provide sewage disposal works.

It was therefore recommended in a report dated October 14, 1921, th immediate action be taken by the proper authorities of the city of Onei to provide works for the treatment of the entire sanitary sewage of city in accordance with the plans approved by this Department on Novem 19, 1913.

On October 15, 1921, copies of the report were sent to the local boa of health of the city of Oneida and the town of Verona, to the sanita supervisor of the district and to the mayor of the city of Oneida. A co munication was received from the city engineer of Oneida on October 1921, in which it was stated that the city intends to sell bonds and proc with the construction of a disposal plant as soon as preliminary investi tions can be made.

PORT LEYDEN

An investigation of alleged objectionable conditions created by the charge of wastes from the factory of the Borden's Farm Products Compa Inc., at Port Leyden, N. Y., into a small stream tributary to the Black Ri canal was made as a result of a complaint to this Department which sta that whey and other refuse from a cheese factory were being discharged i a basin of the Black River canal; that as a result very objectionable od arose from the canal during the hot weather and that the odors were repulsive, that it was impossible to stay on the lawns or porches, or even the houses at times.

The investigation was made on July 5, 1921, by Mr. A. I. Howd of this Division, accompanied by Dr. F. D. Bigarel, health officer of the village of Port Leyden. The factory of the Borden's Farm Products Company, its operation and the disposal of its wastes were carefully examined, the creek and Black River canal and their surroundings were inspected and the superintendent of the factory, the complainant and people living in the vicinity were interviewed.

Port Leyden is an incorporated village having a population of 706, according to the census of 1920 and is located in the southeastern part of Lewis county. The village has a public water supply derived from two streams a few miles east of the village, but has no sewerage system. Practically all of the houses in the village are supplied with water from the public water supply and about 90 per cent are provided with flush closets. Of the properties provided with flush closets a large number dispose of the sewage by leaching cesspools, a few having settling tanks and small subsurface irrigation systems. The sewage from many properties along the Black River canal is discharged directly into the canal without treatment. The soil in the village is said to be sandy and sandy loam.

It was found from the recent inspection that the Black River canal runs through the center of the village in a northwesterly direction. For its entire length through the village a large number of houses and buildings are situated within a relatively short distance of the canal, the sewage from which is generally discharged directly into the canal without treatment.

The factory of the Borden's Farm Products Company, Inc., is located in the northwestern part of the village a short distance from a small stream. The factory is engaged in the shipping of milk and the manufacture of cheese, employing about 6 men. The maximum amount of milk received at the factory is about 34,000 pounds daily, while at the time of the inspection about 25,000 pounds were being received. About the first of June the manufacture of cheese was discontinued and at the time of the inspection all the milk was being shipped. The factory obtains its water supply from the public supply of the village of Port Leyden. A flush closet is provided for the use of the employees, the sewage from which is discharged with the wastes into the small stream near the factory.

When cheese was being manufactured there were two classes of wastes produced, namely, the whey and the waste water and washings from the floors, cans and apparatus. These wastes were discharged from the factory directly into the stream.

When milk is being shipped the wastes to be disposed of consist principally of the wash water from the floors, cans and apparatus. The wash water is collected by floor drains and discharged through a 3-inch tile pipe into a small stream a few hundred feet west of the factory.

The stream into which the waste water and washings are discharged, has a very small drainage area and a very small flow above the point of discharge of the wastes. The stream apparently rises in the village probably ½ mile west of the factory of the Borden's Farm Products Company. After passing the factory the stream flows in a roundabout course to a point about ½ mile from the factory where it empties into the Black River canal. The Black River canal empties into the Black River a few miles north of Port Leyden. Above the factory of the Borden's Farm Products Company the stream is fairly clear. Below the factory the stream is cloudy and contains a thick foam and scum characteristic of small streams into which wastes from creameries have been discharged. In the immediate vicinity of the stream the usual objectionable odors rising from decomposing milk wastes were noticeable. There was practically no wind at the time of the inspection and the odors which were detected near the stream could not be detected any appreciable distance therefrom.

The Black River canal was not filled with water at the time of the inspection. It was stated by residents living nearby that the canal had been filled this spring but that during the three weeks previous, the water had gradually run out of the canal. There was only a shallow stream of water about 8 or 10 feet wide in the bed of the canal, a large portion of which was covered with a green scum. Matter which appeared to be decomposing wastes was also noticeable. The sewage from a number of houses loc along the canal was being discharged near the top of the bank of the c and running down the side of the canal into the waters thereof. The se from the public school and from a number of residences and buildings in central part of the village is also discharged into the canal. The o of algae, sewage and decomposing milk wastes were detected at diffe points along the canal. It seemed evident that under certain atmosph conditions and a strong wind the objectionable odors rising from the str and the canal might be carried a considerable distance and create ditions of nuisance at times.

The necessity for a sewer system for the village has been pointed ou the local authorities in the past. At the present time the need of suc system is still more evident. The village authorities should therefore, em a competent sanitary engineer to prepare plans for a comprehensive sewe system and a sewage disposal plant for the village, only the more neces portions of which would need to be constructed at the present time. discharge of sewage into the Black River canal from residences, the sc and other buildings in the village should be discontinued.

In view of the above facts the following conclusions were drawn in a re dated August 17, 1921:

1. That the factory of the Borden's Farm Products Company, Inc., discharging sewage and wastes into a small creek and the Black R canal in the village of Port Leyden, creating objectionable condition
2. That the sewage from the public school and from a large numbe private residences and buildings in the village is being dischar through private sewers into the canal creating insanitary conditio

It was accordingly recommended:

1. That the Borden's Farm Products Company provide cesspools the disposal of waste water and washings from their factory at Leyden or that the wastes be disposed of by some other satisfact method.
2. That the sewage from the factory of the Borden's Farm Produ Company be disposed of by separate leaching cesspools or by some ot satisfactory method.
3. That plans for the disposal of sewage and wastes from the fact of the Borden's Farm Products Company be submitted to the St Engineer for approval and that the application for the issuance o permit be made to this Department.
4. That when the cheese is being made at the factory, all the w be taken away for feeding or fertilizing purposes or otherwise sa factorily disposed of.
5. That the village authorities employ a competent sanitary engin to prepare plans for a comprehensive sewerage system for the vill of Port Leyden, which plans should be submitted to the State Engin and Surveyor for approval in accordance with the provisions of chap 510 of the Laws of 1921.
6. That the village authorities make application to this Departm for the discharge of sewage from such a sewerage system.
7. That the local board of health take action in accordance with provisions of the Public Health Law to abate any nuisance created the discharge of untreated sewage wastes into the Black River cana

Copies of this report were sent to the local board of health, to the sanit supervisor of the district, to the village authorities, to the Borden's Fa Products Company, Inc., to the State Engineer and Surveyor and to complainant on August 18, 1921. On August 26, 1921, a communication received from Borden's Farm Products Company in which it was stated t the matter of disposal of wastes in a satisfactory manner would be ta up immediately.

In addition to the foregoing, inspections were made and reports transmitted to the local authorities in cases of stream pollution at the following places:

Adams (town), Adams Center, Butler (town), South Butler, Conewango (town), Conewango Valley, Exeter (town), West Exeter, Gilbertsville, Holland (town), Holland, Johnstown, Orangetown (town), Lederle Antitoxin Laboratories, Pomfret (town), Lilly Dale, Poughkeepsie (town), Vassar College, Red Creek, Savannah, Sennett (town), Throop Station, Sharon Springs, Westmoreland (town), Bartlett Station, and Wolcott.

STIGATIONS NOT ARISING FROM STREAM POLLUTION

INVESTIGATIONS OF PUBLIC NUISANCES NOT ARISING FROM STREAM POLLUTION

This Department receives each year numerous complaints against the existence of conditions of nuisance. The matter of the abatement of nuisances is definitely placed within the jurisdiction of the local board of health both by the Public Health Law and the Sanitary Code. In a great many cases a proper abatement of the nuisance is obtained by referring the matter to the local board of health.

Because of the technical features involved, or when the local board of health is unable to secure a satisfactory abatement of the nuisance, this Department is frequently called upon to assist with advice or by an inspection and report.

Insanitary methods of garbage disposal, emission of smoke and fumes from industrial plants and improper disposal of creamery wastes are among the many forms of nuisance which cause complaints and frequently require investigations. The reports of the investigations made by this Department in a few cases which have come before it during 1921 are given below and a list is appended of all other cases.

MT. VERNON

An investigation of alleged objectionable conditions created by the maintenance of a refuse dump in the city of Mount Vernon was made on June 7, 1921, by Mr. A. I. Howd, assistant engineer in this Department.

Mount Vernon is a city having a population of nearly 43,000 and is located in the extreme southern part of Westchester county adjacent to the New York City line. The main lines of the New York, New Haven and Hartford railroad and the Harlem Division of the New York Central railroad pass through the city. The Bronx river flows in a southerly direction through the western part of the city and the Hutchinson creek (or Eastchester river) forms the eastern boundary line of the city.

The refuse dump of the city of Mount Vernon, concerning which complaint was made, is located in the southeastern part of the city on an area of land near the Hutchinson creek opposite the village of Pelham Manor. The locality is sparsely populated. The nearest house in Mount Vernon is about 350 feet west of the dump and there are relatively few houses within a half mile of it. The nearest house in Pelham Manor is probably one-half mile from the dump.

The following facts were collected at the time of the recent inspection. The contractor for the collection of refuse in the city of Mount Vernon has failed and the collection and disposal of the refuse is being done by the city. The residents of the city are required to separate the garbage, ashes and rubbish, but all are dumped into the same wagon and become mixed at the dump. There are 8 large wagons (holding 4 or 5 yards) and one small wagon used for the collection of refuse in the city. About 25 loads of refuse are collected and dumped daily.

The privilege of reclaiming salable materials from the dump is let to contractors who pay the city a certain amount per month. They level the dump and reclaim rags, bottles, rubber and other salable materials. One of the contractors who was interviewed stated that they are required to cover the dump with earth or ashes when furnished with them by the city.

The site used by the city for the dumping of refuse is located just south of the Mount Vernon sewage disposal plant. At the time of the inspection the dump, which was of an irregular shape, was about 200 feet long and varied in width from 50 to 150 feet. The dump contained large numbers of tin cans, great quantities of papers, and rubbish of all descriptions and piles of garbage. It was learned that the dump had been ignited Saturday, June 4. It was still smoldering at the time of the inspection and dense clouds of smoke were carried a considerable distance by the strong wind that was blowing and odors of burning garbage were distinctly noticeable a few hundred feet from the dump.

Owing to the fire on the above site, it became necessary on Monday, June 6, to dump refuse north of the sewage disposal plant. A relatively large area of land north of the plant had already been filled in by refuse during the past few years. The dump contained very large amounts of papers, piles of garbage and rubbish. The refuse was being leveled as soon as dumped and salable matter was being salvaged. No attempt apparently has been made to cover the dump with ashes or earth for some time since large areas remain exposed. The characteristic objectionable odor of decomposing garbage and of rubbish was noticeable several hundred feet from this dump. When on the dump the odor of fresh garbage could be plainly detected.

It was learned at the time of the inspection that the city authorities are considering the construction of an incineration plant. If the authorities have carefully investigated the various methods of garbage disposal and have found the incineration method most suitable to their case, immediate action should be taken by them to have the plant constructed. If an incineration plant is properly constructed and carefully operated, opportunity for the creation of conditions of nuisance would be reduced to a minimum.

In a report dated June 22, 1921, the following conclusions were drawn:

1. That the city of Mount Vernon maintains a refuse dump in the southeastern part of the city.
2. That apparently no attempt has been made for some time to cover the dump with clean ashes or earth, as a result of which quantities of decomposing and decomposable garbage remain exposed on the dump.
3. That flies may breed on the dump and may constitute a menace to the health of the residents in the section of the city in which the dump is located as well as of the residents of nearby communities.
4. That the dump in its present condition creates conditions of nuisance at times which may be detrimental to the public health.
5. That the city is considering the construction of an incineration plant for the disposal of the garbage.

It was therefore recommended:

1. That immediate action be taken by the city authorities of Mount Vernon to put the dump, located along Hutchinson creek in the southeastern part of the city, in a proper sanitary condition, by covering the entire dump with clean ashes or earth, or by some other satisfactory method.
2. That immediate action be taken by the city authorities to construct the proposed incineration plant, provided it has been determined after careful investigation by the city authorities that incineration is the most feasible method of disposal of garbage for the city.
3. That, pending the construction of the incineration plant, the city collect garbage in wagons or trucks separate from the rubbish and ashes and dump the garbage at the bottom of the dump so that it may be covered immediately with rubbish and finally with clean ashes or earth.

Copies of this report were sent to the local board of health, to the sanitary supervisor, to the commissioner of public works of Mount Vernon and to the complainant on June 23, 1921.

PORT CHESTER

An investigation of the alleged nuisance created by the maintenance of a refuse dump by the village of Port Chester, Westchester county, was made by Mr. C. A. Holmquist on September 15, and 22, 1921, as a result of complaints received by this Department. The inspection was made in company with Mr. C. E. Smith, member of the board of trustees, and Mr. Wilcox, the village attorney, was interviewed.

The village of Port Chester, which has a population of some 17,000 according to the last census, is situated in the western part of Westchester county on Long Island sound and the Byram river, the latter stream forming part of the boundary line between the State of New York and the State of Connecticut. An inspection of the public dump of the village with special reference to the objectionable conditions created by fires on the dump was made by a representative of this Department on December 15. 1920. It was found that although fires had frequently occurred on the dump in the past giving rise to objectionable conditions from smoke and odors steps had been taken by the village authorities to prevent the occurrence of fires on the dump in the future and that the village was planning to install an incinerator for the purpose of destroying its garbage and other refuse. The matter of maintaining the dump in a sanitary condition and preventing the recurrence of fires was taken up by the village authorities at that time and we were assured by them that every effort would be made to maintain the dump in a satisfactory condition.

On August 16. 1921, plans for an incinerator to care for the garbage and rubbish of the village were approved by this Department. At the time of the recent inspection on September 15, it was learned that the village had advertised for bids for the construction of the incinerator but that all bids received were considered too high and had therefore been rejected. It was stated by Mr. Smith, village trustee, that bids for the construction of the incinerator would be advertised and the contract awarded as soon as possible.

It was found from the recent inspection that the entire refuse of the village, including ashes, garbage and rubbish, is collected by a contractor and dumped in the marshy and shallow waters in the village at the head of an arm of Long Island sound on the southerly side of Fox Island road opposite Byram Point, Connecticut. The dump is situated in a fairly sparsely settled section of the village. The municipal sewage disposal plant, consisting of a 2-story settling tank and sludge drying beds, is located about 200 feet north of the dump and the factory of R. R. Mallory & Co., Inc., is situated across the road on the easterly side of the dump. There is also 1 dwelling in Port Chester about 600 feet from the dump but it is not visible from the dump on account of an intervening hill. Between ⅛ and ¼ of a mile from the dump are some 10 residences in Connecticut, situated on the easterly side of the Byram river.

This dump which has been used for the disposal of rubbish by the village for a considerable time covers an area of about 1 acre and the refuse has been deposited on this area from a depth of a few feet to some 15 feet at the outer edge. The old portion of the dump has been covered with sand and gravel and presented a satisfactory appearance and gave rise to no objectionable odors. The outer and newer portion of the dump, however, where the material is being deposited at present, forming a crescent shaped area some 200 feet long and from 2 or 3 feet to some 15 feet wide, had not been covered with soil and the mixture of garbage, ashes and rubbish was exposed to the air at the time of the first inspection. Although a disinfectant was being applied to the wastes in order to prevent the propagation of flies, there were numerous flies on the dump.

A very objectionable odor was given off by the garbage, rubbish and disinfectant from the exposed portions of the dump at the time of the first inspection on September 15, 1921. This odor was very objectionable at a considerable distance from the dump and constituted a public nuisance. Objectionable odors were also given off from a smoldering subsurface fire near one edge of the dump. Attempts made to extinguish this fire had not been entirely successful.

The bottom of the outer portions of the dump is below the high-water mark and there is nothing to prevent some of the garbage and rubbish from being washed away and becoming stranded on the adjacent shores by wind and wave action. A bulkhead should be constructed to confine the refuse and keep it from being washed away.

It was pointed out to the representatives of the village interviewed at the time of the inspection on September 15 that immediate steps should be taken by the village to cover the exposed portions of the dump with soil to a depth of from 6 to 10 inches to prevent the escape of odors. It was also pointed out that the refuse should not be spread over a large area as was the practice at that time but that it should be confined to a small area not more than 10 feet square and that this area should be covered with a thick layer of sand or soil each day so that none of the garbage and rubbish would be exposed to the atmosphere. Any disinfectant that may be applied to the rubbish should be added just before the material is covered with the sand and none of it should be spread over the surface of the ground as the disinfectant used gives off an objectionable and disagreeable odor.

At the time of the second inspection on September 22, 1921, it was found that although the conditions at the dump had been improved somewhat the nuisance had not been abated. The exposed portion of the dump had been covered with a thin layer of sand but the covering was not sufficiently thick to entirely cover the garbage and other wastes or to prevent the escape of objectionable odors. The smoldering fire in the dump had not been entirely extinguished and no bulkhead had been constructed to confine the wastes and prevent them from being washed away.

Considering the fact that the present dump is located relatively near the built-up sections of both the village of Port Chester and Byram Point the greatest care should be exercised in maintaining the dump in such a manner as not to create a nuisance until the proposed incinerator is installed. If it is found to be impracticable to maintain the dump in a satisfactory sanitary manner some other site or method of disposal should be adopted.

It was therefore recommended in a report dated September 26, 1921:

1. That every effort be made by the village to hasten the awarding of the contract for and the construction of the proposed garbage and rubbish incinerator or to provide for some other suitable and sanitary method of disposal of its garbage and other refuse.
2. That all exposed refuse on the dump be properly covered with a layer of sand or soil sufficiently deep to permit the escape of objectionable odors and in no case less than 6 inches deep.
3. That until the incinerator is installed and put in operation or some other method of disposal is adopted the village authorities require that the present dump near Fox Island road be covered with a layer of sand or soil not less than 6 inches deep as soon as the refuse is deposited so that it will not be exposed to the atmosphere.
4. That if the present dump cannot be so maintained as to prevent the creation of a nuisance some other site more remote from the built-up sections, not only of Port Chester itself but also from Connecticut, be selected for the disposal of the refuse of the village.

Copies of this report were sent to the village authorities, to the complainant, to the health officer and sanitary supervisor on September 26, 1921, and the matter of carrying out the recommendations of this Department was taken up with the village.

In addition to the foregoing, inspections were made and reports transmitted to the local authorities or advice was given by correspondence in the matter of abatement of nuisances at the following places: Bay Shore, Bedford (town), Katonah, Candor, Concord (town), East Concord, Eastwood, Floyd (town), Granville (two inspections), Hempstead (town), Inwood, Ilion, Lawrence, Liberty (town), Milford, Newcastle (town), Chappaqua, New Rochelle, Pleasantville, Rosendale, Rye, Schenectady, Syracuse, Ticonderoga (town), Unadilla, Villenova (town), Westmoreland (town), Bartlett Station, and White Plains.

SPECIAL INVESTIGATIONS

INVESTIGATION OF SANITARY CONDITION OF STATE INSTITUTIONS

The work of examination of the sanitary condition of the institutions of the State, which this Department is required to make under the provisions of Section 14 of the Public Health Law, has been continued during 1921 so far as the facilities of the division permitted. These examinations are confined to the water supply, sewerage and sewage disposal, refuse disposal and milk supply of the institutions visited. Reports prepared upon these examinations, containing a description of the existing conditions together with the conclusions and recommendations of this Department in regard to the correction of insanitary conditions are transmitted to the authorities having charge of the institution, as required by the Public Health Law.

During 1921 the sanitary condition of the following twenty-four state institutions was examined and reported upon:

Albion (Western House of Refuge for Women).
Alfred (State School of Agriculture).
Auburn (State Prison).
Batavia (State School for the Blind).
Beacon (Matteawan State Hospital).
Bedford (State Reformatory for Women).
Brooklyn (State Hospital).
Buffalo (State Hospital).
Central Islip (State Hospital).
Comstock (Great Meadow Prison).
Elmira (State Reformatory).
Hudson (State Training School for Girls).
Newark (State School for Mental Defectives).
New York City (Randalls Island-New York House of Refuge).
New York City (Wards Island-Manhattan State Hospital).
Ogdensburgh (St. Lawrence State Hospital).
Ossining (Sing Sing State Prison).
Poughkeepsie (Hudson River State Hospital).
Rochester (State Hospital).
Rome (State Custodial Asylum).
Syracuse (State Institution for Feeble Minded Children).
Utica (State Hospital).
Willard (State Hospital).
Wingdale (State Prison).

INVESTIGATIONS OF SEWAGE DISPOSAL PLANTS

The investigations of municipal, institutional and private sewage disposal plants and works for the treatment of trade wastes have been confined during 1921 almost entirely to the inspection of plants concerning which complaints have been made to the department, or which were involved in questions of public water supply, or where requests have been made by the authorities in charge of the plants or by local boards of health for an investigation.

In each case a careful description of the construction and operation of the plants is obtained in the field and a report is prepared containing recommendations for any improvements necessary in the construction and operation of the plants. A copy of the report upon the investigation is transmitted to the local board of health, the sanitary supervisor of the district and to the local officials in charge of the plant.

The reports upon the investigations made by this Department in a few of the more important and typical cases of sewage disposal which have come before it during 1921 are given below and a list is appended of all other cases.

BOLTON (Town) Fenimore Hotel

An inspection of the disposal plant at the Fenimore hotel, Bolton Landing, Lake George, was made on September 27, 1921, at the request of the local health officer and the chairman of the committee on sanitation of the Lake George Association.

Fenimore hotel is located at Bolton Landing about 100 feet from the shore of Lake George and opposite Green Island. The hotel has sufficient capacity to accommodate about 40 guests. The water supply of the hotel is obtained from springs and is supplied to the hotel by gravity flow.

The sewage from the hotel is at present disposed of in 2 cesspools. One of these cesspools serves the laundry and is located back of the hotel at a considerable distance from the lake. It was claimed that this cesspool has operated satisfactorily. The other cesspool which serves the bathroom and kitchen is located under the front lawn between the hotel and lake shore. It appears that considerable trouble has been experienced in the past from the overflowing of the latter cesspool and that the local board of health and committee on sanitation advised the owner of the hotel to remedy these objectionable conditions created by such overflow and to install a new disposal plant which she has proceeded to do. The plans for the proposed plant, however, were not submitted to the State Engineer for approval inasmuch as neither the owner nor the local authorities were familiar with the provisions of the Public Health Law regarding the approval of plans and the issuance of permits for disposal of sewage.

This plant which was under construction at the time of the inspection is to consist of a new settling tank, the existing cesspool and 4 so-called filters or modified underdrained subsurface irrigation systems to be operated in series. The underdrain in the last filter is to discharge into Lake George. All but the settling tank and the first filter had been installed at the time of the inspection. The settling tank which is to be an enamel lined tank is to be divided into three compartments having a total capacity of 860 gallons. The filters are of different sizes but of similar design. The first filter is to be 10 feet x 6 feet x 18 inches deep. The three remaining filters are to be 10 feet x 6 feet x 18 inches deep; 25 feet x 6 feet x 18 inches deep and 6 feet x 6 feet x 5 feet deep respectively. The filter material consists of layers of cinders, gravel and sand placed and in the order named from the top to the bottom. The distributing system at each filter consists of lines of tile laid below the surface of the filter near the inlet of each bed. The lower third of each filter bed area is to be underdrained by a similar system of tile. The second filter bed is located in gravelly soil and the third filter bed is located partly in gravel and partly in clay.

As planned, the sewage from the sink and bathroom, estimated at 35 gallons per day per capita, is to be passed through a proposed metal settling tank, then through the first filter, then through the existing cesspools and then in series through the three so-called filters. The successive beds are so located that the underdrains from the upper filter will discharge into the distributing system of the succeeding lower filter. The underdrainage from the last filter is to be discharged into the lake. The plant was not completed and had not been put in operation at the time of the inspection. The hotel was being closed for the season.

It was pointed out to the owner of the hotel and to the local authorities that although disposal plants serving summer hotels may be operated at somewhat greater rate for a few months in the summer than when serving hotels open all the year round it was apparent that the proposed filters as designed, especially the first filter, were of inadequate size and would in all probability clog quickly in which case the sewage would probably break through the surface of the ground and create objectionable conditions. It was suggested therefore that the construction of the disposal plant be deferred until plans for the system are submitted to and receive the approval of the State Engineer as provided by chapter 510 of the Laws of 1921.

The following recommendations were therefore made in a report dated October 5, 1921:

1. That the work of constructing the disposal plant be suspended until plans for the system are submitted to and approved by the State Engineer.
2. That no permit be issued by the State Commissioner of Health until plans for the proposed system are approved by the State Engineer.
3. That before any sewage disposal plant is constructed at Lake George, plans for such plant be submitted to and receive the approval of the State Engineer.

On October 10, 1921, copies of the report were sent to the owner of the hotel, to the local board of health, to the Lake George Association, and to the State Engineer.

MT. MORRIS

An investigation of the sewerage and sewage disposal systems of the village of Mount Morris with special reference to the alleged nuisance created by the discharge of effluent from the village sewage disposal plants into a tail race which runs through the eastern part of the village was made on December 1, 1921, as a result of a complaint received by the Department to the effect that the tail race into which the effluent is discharged has been abandoned so that there is little or no water flowing in it with the result that a nuisance affecting the health of the tenants of a large farm below the plant is created.

The village of Mount Morris which has a population of about 3,300 according to the last census is located in the western part of Livingston county near the confluence of the Genesee river and Canaseraga creek. It is provided with a public water supply which serves practically the entire village. The water supply, which is obtained from Silver Lake, is passed through pressure mechanical filters and chlorinated before it is delivered to the mains. The daily water consumption is estimated at from 500,000 to 700,000 gallons per day of which the Delaware, Lackawanna and Western railroad uses about 200,000 gallons per day. The average water consumption, therefore, ranges from 90 to 150 gallons per capita per day.

The records of the Department show that the original plans for a separate sewer system and for a sewage disposal plant consisting of septic tanks and intermittent sand filters to be located on the flats east of the Pennsylvania track near the foot of Murray street extended were approved on September 1, 1905. These plans, however, were not carried out and on November 10, 1914. amended plans for sewerage and sewage disposal were approved after having been revised to meet our requirements.

The amended plans provided for modifications and additions to the original sewer system and for the installation of two sewage disposal plants each consisting of an Imhoff tank and a sludge drying bed in place of the septic tanks and sand filters originally planned. The small tank which was to be located on the southerly side of State street some 500 feet below Mill street was designed to care for an ultimate population of 700. The large tank was designed to care for an ultimate population of about 3,100. The effluent of these two plants was to discharge temporarily into the tail race a short distance above the culvert under the Delaware, Lackawanna & Western railroad tracks. The plans however showed an 18-inch outlet sewer extending from the temporary outlet to Canaseraga creek, a distance of about 1 mile below the temporary outlet. The plans also included general plans for sand filters. Permission was granted to temporarily omit the construction of the sand filters and the portion of the outlet sewer below the railroad.

It was found from the recent inspection that the sewerage and sewage disposal systems had been constructed in 1915 in substantial conformity with the approved plans. It was estimated that about 75 per cent of the population or about 300 persons are connected with the sewer system. About 2,250 persons served by sewers contribute sewage to the main sewage disposal plant located on the easterly side of the Pennsylvania railroad near Murray street. About 150 persons are served by sewers connected with the small plant.

The inspection of the main disposal plant showed that it was producing a fairly satisfactory effluent. The settling compartment of the tank was, however, covered with a thick blanket of scum and it appeared that it has not been the practice to remove the scum which accumulates in the settling compartment. It is important that the scum be removed at least every other day and not be allowed to accumulate in this compartment as a large portion of it will ultimately be carried over the weir into the effluent pipe if not removed. The scum removed from the settling compartment could appropriately be deposited in the shaft connected with the sludge compartment. The sloping sides of the partitions between the settling compartment should also be squeegeed not less than once a week in order to prevent the accumulation of sludge on these sloping walls.

It was learned that it has been the practice to remove the sludge from the large settling tank only twice a year, early in the spring and late in the fall. Although with the relatively small population served by the settling tank at present this practice has probably not seriously interfered with the operation of the tank. Better results would, however, be obtained if the sludge were removed at intervals of not less than six weeks or two months between April and November. It should not be necessary and would probably not be advisable to remove any sludge between the first of December and the first of April, inasmuch as the sludge would not dry out during freezing weather to a sufficient extent to permit of its removal from the sludge bed by spading. The sludge found on the drying bed, which it was claimed had been removed from the tank about November 1, still contained considerable moisture which however was probably due in part to the recent heavy rains. No objectionable odors were observed coming from the sludge bed except in the immediate vicinity of the bed when in line with the wind from the bed.

An inspection of the small tank indicated that it is practically in the same condition as the large tank. There was considerable scum in the settling compartment. This scum should be removed regularly and not allowed to accumulate. From a statement made by the superintendent of waterworks, who has charge of the operation of the plant, it appears that sludge has been removed from the small plant only once or twice since it was constructed in 1915. Although only about one-quarter as many people are served by this plant as the design called for the sludge should be removed regularly as in the case of the large tank.

An examination of the outlet from the disposal plant and the tail race showed that the flow in the tail race was entirely inadequate to provide for sufficient dilution of the effluent to prevent the creation of a nuisance. Although there had been very heavy rains for a few days before the time of the inspection there was less than twice as much water flowing in the tail race as effluent discharged into it. A large area of the bed of the stream between the outlet of the disposal plant and the culvert under the railroad bridge was covered with sludge in a state of putrefaction. This accumulation of sludge was due partly to the fact that the settling compartments of the settling tank are not kept free from scum thereby allowing solids to be carried out over the outlet weirs but principally to the fact that there is at present insufficient flow in the tail race to dilute the effluent and carry it down to Canaseraga creek. The visual effects of the pollution of the tail race disappeared before the confluence of the tail race with the creek. This was due largely to the high water in Canaseraga creek from the recent heavy rains which had caused the water from the creek to back up into the tail race and partly to the turbid nature of the creek.

When the plans for sewerage and sewage disposal were submitted for approval we were advised by the designing engineer that during the summer months nearly the entire flow of the Genesee river was diverted and carried into the power canal above the tail race and that the minimum flow in the tail race was at that time about 100 cubic feet per second. It was considered that this flow was more than adequate to provide for a proper dilution of the effluent from the settling tanks and that no nuisance would be created. Some three years ago, however, a hydroelectric power plant was constructed at the dam in the Genesee river near the head of the old power canal and during the past summer the entrance to the old power canal has been closed and all of the water from the Genesee river has been used either for power purposes at the new power plant, the tail race of which discharges into the river and not through the old power canal or has passed over the dam. The only flow reaching the tail race has been that due to a slight leakage in the gate near the river and from the contribution of a very small stream which flows through the central portion of the village and empties into the old hydraulic canal. This flow is entirely inadequate to provide for a satisfactory dilution of the effluent from the disposal plant.

At the time of the inspection the power plant was using only a portion of the flow of the Genesee river and large quantities of water were flowing over the dam and wasted. It would appear that during a large part of the year the flow in the river is in excess of that used by the power plant and that sufficient water could probably be diverted into the old hydraulic canal and tailrace to dilute the effluent from the village disposal plants and prevent the creation of a nuisance until the effluent pipe can be extended to Canaseraga creek.

One of the tenants on the farm located above the point of discharge of the tail race into Canaseraga creek was interviewed. It was stated by her that during the past summer and until the recent high water occurred in Canaseraga creek, which caused the backing up of water from the creek into the tail race, a very serious nuisance was created which affected not only herself but also her neighbors. It was alleged that the water supply of the farm which was formerly derived from a driven well located near the farmhouse, about one hundred feet from the tail race, had become so polluted by seepage from the tail race that it has been necessary to abandon the use of this water for drinking purposes. It was also claimed that until the water entering the tail race was shut off last spring no nuisance was created by the discharge of effluent from the disposal plants of the village.

It was therefore recommended in a report dated December 12, 1921:

1. That the village authorities be notified to extend the effluent pipe from the disposal plants to Canaseraga creek as provided by the approved plans and stipulated by the permit issued in connection with these plans and to have this effluent pipe in operation on or before June 1, 1922.

2. That until the effluent pipe can be extended to Canaseraga creek, the village authorities arrange with the power company, if possible, to divert sufficient water to the old hydraulic canal and tail race to dilute the effluent and prevent the creation of a nuisance.

3. That the operation of the disposal plants be modified in the following respects:

   (a) That the scum which accumulates in the settling compartments of the settling tanks be removed not less than once every other day.

   (b) That the sloping wall of the partitions between the settling and sludge compartments be squeegeed at least once a week.

   (c) That the sludge be drawn from the settling tanks at least every six or eight weeks between the months of April and November.

Copies of this report were sent on December 16, 1921, to the village authorities, to the local health officer and to the complainant. On the same date the municipal board of the village of Mount Morris was notified to extend the outlet pipe shown by the plans approved on November 10, 1914, from the temporary outlet near the Delaware, Lackawanna and Western railroad bridge to Canaseraga creek and to have said outlet pipe completed and put in operation by June 1, 1922.

PELHAM

An investigation was made by Mr. A. I. Howd of this Department on June 7, 1921, of the sewage disposal plant of the town of Pelham, Westchester county, N. Y.

The town of Pelham is situated in the southcentral part of Westchester county a short distance north of New York city between the city of Mount Vernon on the west and the city of New Rochelle on the east. The incorporated villages of Pelham, North Pelham and Pelham Manor comprise the town. They are provided with a water supply furnished principally by the New Rochelle Water Company, practically all of the residents being supplied. The town has a population of about 5,000.

The sewage disposal plant for the town is located in the village of Pelham Manor on the east side of the Hutchinson river. The disposal works consist of a screen and grit chamber, settling tanks, pumping plant, dosing tank and sprinkling filters. Previous inspections of the operation of the plant have been made by this Division in 1914 and 1918.

The whole of the village of Pelham and all of North Pelham are served by sewer systems tributary to the Pelham sewage disposal plant except a small area of about 30 acres, comprising about one-tenth of the area of North Pelham, the sewage from which is discharged into the Mount Vernon sewer system. The sewage from a small area in the southern part of Pelham Manor is discharged into a series of so-called liquefying tanks, the effluent from which is discharged into Long Island sound. The sewage from about 35 per cent of the area of the village of Pelham Manor flows by gravity to a pumping station, known as the Mt. Tom pumping station, from which it is pumped through 2,000 feet of force main to a point on Pelhamdale avenue where it empties into a sewer which carries it by gravity to the Pelham sewage disposal plant. The remainder of the village is served by a gravity system which conducts the sewage to the main sewage disposal plant.

The sewage from the different sections of the town flows through three main trunk sewers to a manhole outside the sewage disposal plant. There is a by-pass from this manhole through which raw sewage may be discharged direct into the creek. The by-pass is provided with a valve which will prevent sewage being discharged into the creek except at the discretion of the operator of the plant, but which does not prevent water from the creek backing up into the sewage disposal plant at times of high water.

The sewage enters the disposal plant through a screen and grit chamber located under the floor of a building which also houses the settling tanks, pumping plant and dosing chambers. The screens, which are of the bar type, were so clogged at the time of the inspection that the sewage was running over the top of the screens. It was learned from the attendant at the plant that the screens had not been cleaned for a considerable time and that the grit chamber was cleaned about two months previous to the inspection. According to the attendant, the grit chamber is cleaned about every three months, the cleanings being buried near the plant. The clogging of the screens caused the sewage to back up in the sewers approaching the plant, a manhole 300 or 400 feet from the plant being virtually filled with sewage.

The settling tanks are divided into four units, the two northerly units being in operation at the time of the inspection. The capacity of the two units is about 78,600 gallons which provides an average detention period for the sewage of about 2 hours. These units had been in continuous use for about two months. A considerable portion of the sewage in the tanks was covered with a thick, crusted brown scum. The tanks not in use were filled with water. The sludge is emptied from the tanks from time to time and was said by the attendant to be buried in the ground near the plant.

The dosing tanks and automatic siphons were not operating properly at the time of the inspection. The dosing tanks were not emptied in rotation and the periods of dosing and resting of the filters were irregular. Observations were made about noon which indicated at that time that Bed No. 1 was being dosed for a period of about one minute and was resting for about two minutes between doses. Bed No. 3 was being dosed for periods ranging from 15 seconds to 1 minute 20 seconds and was resting from 1 minute 45 seconds to 2 minutes 40 seconds. Bed No. 2 was not dosed during the observations. Later in the afternoon observations were continued. Bed No. 2 dosed for 5½ minutes evidently for the first time in several hours. About one-half hour later Bed No. 3 was dosed for 6¼ minutes and near the end of the dose Bed No. 1 began to dose and was dosed for nearly 9 minutes. The beds were not dosed again during the remainder of the observations, Bed No. 2 having rested for an hour.

The sprinkling filters were being operated at an average rate of about 1,670,000 gallons per acre per day. It appeared at the time of the inspection that the center unit was operating considerably below this rate and the other two units considerably in excess of this rate. Several of the sprinkler nozzles in the center unit were clogged and in need of cleaning.

The effluent from the sprinkling filters was somewhat cloudy but apparently free from large particles of suspended matter. The stream into which the sewage is discharged is grossly polluted and the black muck on the banks of the creek presents a very unsightly appearance at low tide.

It was evident at the time of the inspection that the sewers were receiving excessive amounts of ground water and probably large quantities of storm water. This condition was plainly noticeable at a manhole on Pelhamdale avenue where sewage empties from the force main from the Mt. Tom pumping station into the gravity system. The sewage was quite clear and at the time free from any large particles.

It was impossible at the time of the inspection to make satisfactory observations as to the distance from the plant at which odors might be detected. While the inspection was being made at the plant, the wind was in the east carrying any odors that might arise across the river toward Mount Vernon. An attempt was made during the afternoon to observe odors from the Mount Vernon shore but before any satisfactory observation was made the wind shifted to the west.

It is evident as a result of the inspection that the sewage disposal plant of the town of Pelham is not being satisfactorily operated and several conditions should be immediately remedied.

The by-pass to the river from the manhole on the main sewer leading to the plant and located just outside the main building, should be removed or satisfactorily sealed. Its existence and use defeats the purpose for which the sewage disposal plant was constructed and is being operated, and furthermore, the discharge of raw sewage into the Hutchinson river through this by-pass is a violation of the public health law. This Department has recommended a number of times in the past that this by-pass be removed or sealed.

The screens in the screen and grit chamber should be cleaned several times a day or as often as is necessary to prevent sewage flowing over screens and so that they may be used for the purpose for which they were intended. The screenings should be removed and disposed of in a satisfactory sanitary manner. Under no condition should the screenings be pushed or discharged into the channel leading to the settling tank or be discharged into the Hutchinson river.

The discharge of sewage from the pumps into the dosing tanks should be more evenly regulated. It appeared at the time of the inspection that the middle dosing chamber received less sewage than the other chambers, since the middle sprinkling filter unit discharged less often than the end filter units. This lack of uniformity of distribution of sewage to the dosing tanks might possibly be corrected by increasing or decreasing the size of the openings from the distribution channel to the various dosing tanks.

The siphons, particularly those serving Bed No. 1 and Bed No. 3, should be overhauled and put in a proper operating condition so that all the sewage in the dosing tank shall be discharged in one dose and not allowed to dribble intermittently for several minutes.

In a report dated July 23, 1921, the following recommendations were made:

1. That the by-pass allowing raw sewage to pass directly to the Hutchinson river be entirely sealed up or removed and if any overflow is deemed necessary, that an overflow be provided for the effluent from the settling tanks to be used only in case of emergency such as the breaking down of the pumps.
2. That the screens be cleaned regularly and as often as may be necessary to prevent their clogging.
3. That provision be made for the disposal of the screenings in a sanitary manner.
4. That the openings in the distribution channel discharging settling tank effluent into the dosing chamber be so modified that uniform distribution of the settling tank effluent over the sprinkling filters may be effected.
5. That the clogged sprinkling filter nozzles or risers be cleaned.
6. That a competent sanitary engineer be employed to design and prepare plans for a sludge drying bed for the proper disposal of sludge from the plant.
7. That the town authorities in charge of the sewage disposal plant employ a competent sanitary engineer to have charge of the operation and maintenance of the sewage disposal plant.
8. That the town authorities provide for a comprehensive survey of the town to determine from what sources water from catch basins, drains, or roof leaders may enter the sewer system and require the immediate disconnection of all such sources.

Copies of the report were sent to the local boards of health of the town of Pelham and the village of Pelham Manor, to the sanitary supervisor of the district and to the board of sewer commissioners of Pelham.

SARATOGA COUNTY TUBERCULOSIS HOSPITAL

An investigation of the sewage disposal plant of the Saratoga County Tuberculosis Hospital was made by Mr. W. C. Emigh, assistant engineer in this Department, on April 29, 1921. The investigation was made following a communication from A. R. Dimock, M. D., superintendent of the hospital, to this Department under date of April 22, 1921, in which he requested that an engineer visit the hospital to advise regarding the disposal plant.

Plans were approved on August 20, 1913, for a sewage disposal plant to treat the sewage of the Saratoga County Tuberculosis Hospital. The recent inspection by our engineer indicated that, in general, the plant had been constructed in conformity with the approved plans, although a few details of construction differed from those shown. The essential features of the plant comprise a settling tank, a sludge drying bed, a dosing chamber, a sprinkling filter, a final settling tank and a subsurface irrigation system. The plant was originally designed to care for the sewage from 75 persons under the usual assumptions as to quantity of sewage contributed per capita. The plant is located at a distance of about 700 feet from the administration building, but is in somewhat closer proximity to other structures.

The sewage is conveyed from the hospital in a 6-inch sewer to a concrete settling tank, the inlet and outlet of which are each trapped. The tank is 5 x 15 feet in plan with a depth below the flow line of 6 feet. The floor is flat and a shear-gate at the floor level permits the discharge of accumulated sludge on to a sludge drying bed. At the time of the inspection a heavy scum was found in the tank, but no considerable quantity of sludge.

The dosing tank is of concrete, 4 x 5 feet in plan; is located adjacent to the settling tank, and is of integral construction therewith. It is equipped with a 5-inch automatic Miller dosing siphon. Both the settling tank and dosing tank are provided with a concrete roof through which manholes afford access to the interiors. At the time of the inspection it was found that the siphon was not in operation and upon removing the bell the air piping was found to be clogged. It could not be learned that the siphon had operated for a considerable time.

The sprinkling filter is located at a distance of about 30 feet from the dosing tank. It is 15 feet square with a depth below the surface, as shown by the plans, of 5 feet. The plans and report on the examination of same indicate that the filtering medium was to consist of screened gravel, ranging in size from ¾ inches to 2 inches. The distribution system was to be of cast-iron pipe with 4 nozzles of the Taylor square spray type placed 8 feet on centers at the corners of a square. The drainage system consists of 6-inch split tile pipe. It appears that a minimum head on the nozzles of about 2 feet is obtained. A roof is provided over the filter, the underside of which is 4 feet above the surface of the bed. Access to the filter is afforded by manholes fitted with cast-iron frames and covers. At the time of the inspection it was found that the nozzles had been removed or broken and that for some time the sewage had flowed directly on to the surface of the bed. A surface area of 225 square feet is provided by the filter. With a flow of 7,500 gallons of sewage per day and a 5-foot depth of filter, a rate of operation of 290,000 gallons per day per acre per foot of depth of filter results. This rate is within allowable limits.

In order to obtain a satisfactory operation and purification of sewage it will be necessary to thoroughly overhaul the unit and place it in proper condition. The gravel should be entirely removed and if found to be properly graded, as originally specified, may be thoroughly cleaned and replaced. It is possible, however, that it will be found more economical to procure new gravel from local beds. New nozzles should be installed and, if it is found that the distribution system is clogged, it should be thoroughly cleaned. When the gravel is removed the under drainage system should be carefully examined and cleaned if necessary. Although openings are provided in the filter walls it would be advisable to assure a circulation of air by the removal of the manhole covers and the substitution of ventilators with louvres as pointed out in the report on the examination of the plans.

The final settling tank is at the end of the filter and is of integral construction therewith. It is 3 x 15 feet in plan and the floor of the tank, as shown on the plans, is about 18 inches below that of the filter. A considerable quantity of gravel was found in the bottom of the tank, filling it nearly to the level of the underdrains from the filter. The plans show the outlet pipe from the final settling tank flush with the floor of the tank. As pointed out in the report on the examination of the plans, the invert of this pipe should be within an inch or two of the elevation of the floor of the filter. If the pipe was not so placed at the time of the construction it should be done at this time.

On the plans a connection was shown from the final settling chamber to the sludge drying bed, but as the elevation of the floor of the chamber is below that of the surface of the bed, it would not be possible to draw off the accumulated sludge by means of such a connection. Whether or not the connection was installed was not learned but it is important that provision be made for the withdrawal of the sludge. A small sludge drying bed should be constructed at a sufficiently low elevation to permit the sludge from the final settling tank to flow to it by gravity. Such a bed may be constructed with earthen banks at comparatively small expense.

From the final settling tank the effluent flows into a 10-inch vitrified tile pipe with open joints which extends a distance of 100 feet to the brow of a small ravine sloping to a stream. From that point it continues about 300 feet down stream paralleling the brow of the ravine. At a depth of 5 feet below the first pipe line is a second line with open joints intended to act as a sub-soil drain facilitating the absorption of the filter effluent. At the time of the investigation sewage was flowing from the upper pipe through the soil to the ground surface at a point near the first angle in the line and at a second point a short distance down stream from the first. It appeared that, owing to the discharge of unfiltered sewage into the subsurface absorption system, which was originally designed to receive the filtered effluent, the ground had become clogged resulting in the sewage breaking through to the surface.

Inasmuch as the stream is not used as a source of water supply, the plant, if placed in good condition and properly operated with final settlement should produce an effluent which may properly be discharged into the stream. If it is decided to continue the discharge into a subsurface irrigation system the present piping should be flushed or otherwise cleaned and placed in proper condition. It is quite possible that the ground in the proximity of the drains has become so clogged by the discharge of unfiltered sewage that it will become necessary to relocate the system in order to obtain complete absorption. If, on the other hand, the effluent is to be discharged directly into the brook the outfall sewer should be continued to the bed of the stream, thereby avoiding any possible nuisance which may result from the discharge of the effluent on to the ground surface without dilution.

It is important that the necessity for careful operation be appreciated by the attendant. It is also advisable that some supervision be exercised to assure the continued satisfactory functioning of the plant after the needed repairs, alterations and additions have been effected. Plans for all additions or alterations involving a departure from the plans already approved should be submitted to this Department for approval.

In a report dated May 17, 1921, it was pointed out that the plant was constructed in general conformity with plans approved by this Department, but that through lack of attention it has ceased to function properly.

It was, therefore, recommended:

1. That the settling tank be cleaned by the removal of the scum from the surface of the contents.
2. That the automatic dosing siphon be cleaned and placed in proper operating condition.
3. That the filtering medium in the sprinkling filter be removed and either thoroughly cleaned and replaced, or that new material, properly graded, be installed.

4. That new nozzles be installed on the distribution system and that the distribution system be cleaned, if necessary.

5. That the final settling tank be thoroughly cleaned and that the outlet therefrom be raised to an elevation not lower than 2 inches below that of the floor of the filter.

6. That a sludge drying bed be constructed with proper connections for the withdrawal and drying of sludge from the final settling tank, plans for which should be submitted to this Department for approval.

7. That the outfall sewer be extended to discharge into the water of the stream, or that the present subsurface absorption system be cleaned and relaid. If the outfall sewer is extended plans for such extension should be submitted to the Department for approval.

8. That at all times the plant be carefully operated and that intelligent supervision be exercised.

On May 17, 1921, copies of this report were sent to Dr. James S. Walton, sanitary supervisor of the district, and to the superintendent of the hospital.

In addition to the foregoing, inspections were made and reports transmitted to the local authorities or advice was given through correspondence with reference to the disposal of sewage at the following places:

Altamont, Baldwinsville, Chautauqua County Tuberculosis Hospital, Columbia County Tuberculosis Hospital, Copake, East Syracuse, Herkimer County Tuberculosis Hospital, Hoosick (town) (school), Mt. Pleasant (town),Pocantico Hills Estate, Naples (Naples academy), Nassau County Tuberculosis Hospital; Newcastle (town) Children's Convalescent home, New Rochelle, Orangetown (town) Lederle Antitoxin Laboratories, Phillipstown (town) Surprise Lake camp, Pomfret (town) Lilly Dale assembly, Stamford and Yonkers (Colonial Heights).

INVESTIGATIONS OF MILK PASTEURIZING PLANTS

The investigation of the sanitary condition, equipment, and method of operating of milk pasteurizing plants in this State was begun in 1917 and was continued until July, 1921, when, due to the reorganization of this Division, it became necessary to temporarily suspend this work. Some 190 plants were inspected during 1921. The investigation has been confined largely to plants which do not ship their products wholly or in part to the City of New York, and which are not inspected by the New York City Department of Health. A report on the inspection of a plant is, in each case, prepared and transmitted to the owner of the plant and to the local health officer of the community in which the plant is located. In these reports the results of the inspections are set forth, the general sanitary conditions of the plants are described and recommendations for improvements are made. As a result of the carrying out of the recommendations made by this Division in the past the sanitary conditions of milk pasteurizing plants have been greatly improved and a better grade of milk throughout the State has been obtained.

MOSQUITO EXTERMINATION (Nassau County)

The Nassau County Mosquito Extermination Commission has continued the work of mosquito extermination in that county during the year of 1921 as provided by chapter 408 of the Laws of 1916 and in accordance with said law under date of June 28, 1921, submitted to the State Commissioner of Health the annual report of the work of the Commission for the calendar year 1920. The tentative budget of the Commission for the year 1922 was submitted to the State Commissioner of Health for approval under date of August 9, 1921. A list of the property both salt marsh and upland, with a description thereof, upon which the Nassau County Mosquito Extermination Commission proposes to enter during the year 1922 for the purpose of mosquito extermination was attached to the budget. The report referred to is printed below.

The report of the Director of the Division of Sanitation covering the examination of the estimates, plans and methods is also presented below. These estimates, plans and methods were approved by the State Commissioner of Health on September 17, 1921, and forwarded to the Chairman of the Board of Supervisors of Nassau County and to the Nassau County Mosquito Extermination Commission on September 19, 1921.

DR. HERMANN M. BIGGS, *State Commissioner of Health:*

The Nassau County Mosquito Extermination Commission is composed of the following members: Hiram R. Smith, Freeport, L. I., president; Abraham Adelberg, Cedarhurst, L. I., treasurer; Daniel Morrison, Freeport, L. I.; Dr. Arthur D. Jaques, Lynbrook, L. I.; Irving Cox, Mill Neck, L. I.; John T. Pratt, Glen Cove, L. I.; James H. Dayton, Lynbrook, L. I., secretary. The field work is under the supervision of William H. DeMott.

Our work is carried on under the general headings, Salt Marsh, South Shore Upland, North Shore Upland, and Winter Operations. Therefore our report will follow these capitulations.

Salt Marsh

The salt marsh maintenance and patrol work began on April 15, with a crew of 10 men. Our ditched areas were divided into four sections as in 1919. Each section was placed in charge of an inspector who acted as a labor foreman. The 4,685,870 feet of ditches were covered five times at a cost of $9,754.03; 13,619 feet of spurs and 10,643 feet of mains were installed.

A marked decrease of salt marsh mosquitoes was found from Inwood to Merrick, a distance of 11 miles on the South Shore, and no salt marsh mosquitoes on the North Shore from Great Neck to Cold Spring Harbor, a distance of 17 miles. This proves the adequacy of salt marsh drainage work.

South Shore Upland

The work in this district was carried on by a district inspector, four inspectors, a labor foreman, and four laborers.

Following is a summary of their work:

Total number of inspections	4,250
Total number of gallons of oil used	4.500
Total number of times breeding killed	342
Total footage new ditches installed	17.330
Total footage old ditches cleaned	31,330
Total number of swamps drained	13
Total number of swamps lowered	4
Total number of wet areas drained	7

There was a total of 280 violations, 2 of which have been entirely eliminated. Six hundred catch basins were oiled every week.

North Shore Upland

The work in this district was carried on by a District Inspector, and the same number of inspectors and laborers as on the South Shore Upland. On April 16, the inspectors started a spring oiling of all the swamps from Great Neck to Cold Spring Harbor, using 1,325 gallons of oil. This season the swamp mosquito was almost unknown in the county.

The installation of new ditches and the maintenance work was in charge of the foreman with four laborers.

Following is a summary of the work in the district:

Total number of inspections	7,922
Total number of gallons of oil used	11,328
Total number of times breeding killed	1,528
Total footage new ditches installed	10.484
Total footage old ditches cleaned	626,899
Total footage old ditches recleaned	12,425
Total footage pond edges cleaned	5,000
Total number of swamps drained	1
Total number of violations	395

The Mill Pond and Leeds Lake, Manhasset, Mill Pond, Roslyn, Large Pond, North Shore Country Club, and Mill Pond, Oyster Bay were lowered every two weeks. The Public Swamp at Great Neck was drained by installing a marginal ditch, 8,716 feet long, connecting with the brook that runs into Manhasset Bay.

If a comparison is made of the work accomplished in the two upland districts, it should be remembered that the work has been carried on longer on the North Shore than on the South Shore.

The following table shows the breeding percentage in the upland districts:

	South Shore Per Cent	*North Shore* Per Cent
Culex	35	49.2
Aedes	59	12
Anopheles	6	38.8

The main object, particularly on the North Shore, has been the elimination of malaria. The Commission has worked with untiring efforts for the last four years to establish the following record for the county; this shows the number of malaria cases for each year since 1916.

	Previous to 1916	Annually since 1916 1916	1917	1918	1919	1920
New cases	475	56	51	5	3	0

There is no doubt that our work has effected an absolute control of malaria conditions that a few years ago were alarming.

Winter Operations

In previous years it has been the custom to suspend salt marsh work on September 30. This year, using a spade developed by the Chief Engineer of the Commission, we installed 17,605 feet of main 10 x 30 ditches at a cost of 2 cents per foot, and 100,503 feet of spur, 8 x 20 ditches at a cost of 1 cent per foot, with an additional expenditure of $675.00 for measuring, staking, and supervision. The work commenced on October 1st and continued until December 31st. This method of installing our own ditches has proved more economical than letting a contract for the work, and more satisfactory since we can dig ditches in places that cannot be reached by a machine.

On the upland, two inspectors on the North Shore, and two on the South Shore, were employed throughout the winter months. They cleaned ditches and streams, and removed vegetation which can not be removed during the summer months because of the prolific growth. This means was used in order to avoid delay in the usual spring inspection and oiling.

During the inclement weather the District Inspectors worked on maps and charts, and prepared a schedule for the ensuing year. The inspectors worked in the garage assisting the mechanic in overhauling and painting the cars and boats.

The office force consisted of the Chief Engineer, in charge of the work on the field, the Secretary of the Commission, and one confidential clerk and stenographer.

1922 Tentative Budget

In submitting our 1922 tentative budget of $72,000 for estimated expenses, we invite your attention to the proposed plans for the work of the coming year.

An expenditure of $19,260 is apportioned to the Salt Marsh. This sum includes $14,160 for maintenance and patrol of more than 5,000,000 feet of ditches installed from the New York city line on the west, to Seaford creek, Seaford, on the east; $3,000 for the installation of approximately 150,000 feet of new ditches on the mainland and island areas east of Seaford creek, and at High Hill beach, and $2,100 for the salary of a Salt Marsh District Inspector who supervises all salt marsh work in the summer and in the fall, winter, and spring has full charge of the new ditching work. No more salt marsh ditching contracts will be issued by the Commission, as we are installing all new ditches with the hand spades invented by Mr. William H. DeMott, Chief Engineer.

Our upland work is divided into two districts, South Shore and North Shore. The sum of $10,476 is set aside for the South Shore, providing $4,200 for inspection, and oiling when necessary of all ponds, swamps, brooks, and wet areas from Inwood to Freeport; also to maintain an efficient number of men throughout the winter months to patrol; $4,176 for a labor crew consisting of a foreman and six laborers to do maintenance work and a limited amount of permanent elimination over the same territory, and $2,100 for the salary of a District Inspector who supervises the upland work in the summer, and in the winter prepares maps and charts and lays out the plan of work for the coming year.

The sum of $10,476 for the North Shore provides for a District Inspector, four inspectors, and a labor crew whose duties are the same as the South Shore upland force.

The sum of $1,200 provides for two inspectors who will carry on a systematic house to house campaign in the villages of Freeport and Rockville Centre or Lynbrook from May 1 to September 30.

The administration item of $7,000 includes the salaries of the chief engineer, secretary, and clerk.

Operating expenses in the amount of $17,001.50 include the running expenses of the eight cars and four boats, the wages of the mechanic, the overhead costs of garage, boat house, and office rent, boat hire, mosquito oil for temporary extermination purposes, equipment as itemized, insurance, office

expenses, publicity, and supplies which include all tools used in the fi
both upland and salt marsh. These estimates of quantities and expen
tures are all based on the actual amounts and cost of corresponding ite
during the current year.

Five thousand dollars is allowed to drain Beaver swamp, south of
railroad tracks, a bad malaria mosquito breeding place at Mill Neck, L

The contingent fund of $1,586.50 is to cover any unforeseen circumstan
that may arise throughout the year.

Respectfully submitted,

THE NASSAU COUNTY MOSQUITO EXTERMINATION COMMISSI

HIRAM R. SMITH,

Presiden

(A budget with a general description of the proposed amounts for w
to be carried on in 1922 and a list of property owners with a general descr
tion of the property on which the work of the Commission is to be carr
on in 1922 was attached to the above but is not here included.)

HERMANN M. BIGGS, M. D., *State Commissioner of Health:*

I wish to submit the following report upon an examination of the pla
estimates and methods for mosquito extermination work in Nassau cou
for the year 1922, submitted for your approval by the Nassau County M
quito Extermination Commission. The following plans, estimates and pap
were formally submitted on August 31, 1921:

1. A map of Nassau county showing the salt marshes planned to
drained or ditched by the Commission in 1922 and the areas be
drained in 1921. This map also shows the areas drained in the p
those yet to be drained, and the violations under control in the cou
during the season 1920–21.
2. A signed statement or memoranda explaining the plans and meth
of operation proposed by the Commission for 1922.
3. A detailed estimate or budget of moneys required to meet the
penditure proposed to accomplish the work indicated on the plan d
ing the year 1922, and described in the memoranda attached to
estimate.
4. A list of properties, with a general description thereof upon wh
the Nassau County Mosquito Extermination Commission proposes
enter during the year 1922 for the purpose of mosquito extermination
5. Information and instructions in detail as to the methods to be f
lowed in eliminating the local breeding places of mosquitoes are giv
in a copy of a printed notice which the Commission has issued to
property owners.

The total estimate or budget for the ensuing year amounts to $72,0
which is $2,000 less than the budget for the present year. The expenditu
proposed are placed in the budget under the following general headings:

I. Salt marsh district.
II. South shore upland.
III. North shore upland.
IV. House to house inspection.
V. Administration.
VI. Operating expenses.
VII. New drainage work.
VIII. Contingent fund.

It seems that approximately one-third of the budget is to be devoted
marsh and swamp work, one-third to upland mosquito control work and th
the remaining third appears planned to be about equally divided betwe
operating and overhead expenses.

It will be also seen from the comparative annual estimates that wh
approximately the same amount is to be spent for swamp and marsh drain

as during the present year, the marsh ditching will be about one-half that done the previous year, while the swamp cleaning or drainage like the house to house inspection, appears to mark an advanced step on the part of the Commission. The salt marsh drainage proposed will, however, eliminate about half the remaining mosquito marsh between that already treated and the Suffolk county line.

A new feature which is to be noted in the proposed draining or cleaning of breeding places for malarial mosquitoes known as Beaver Swamp. This swamp is located south of the railroad right of way near Mill Neck in the northern part of the county and $5,000 is provided in the budget for its treatment. Another new feature is a provision of $1,200 for intensive house to house inspection during warm weather.

The force planned to be employed consists as during the previous year of 11 employed the year around and about 44 additional men employed during warm weather. No reduction in insurance or in compensation is shown which latter may be explained by the fact that specially trained employees are necessary to do this specialized work and most employees are only engaged during that part of the year when more attractive work is plentiful. Beside these men others will be employed by contract on work in Beaver Swamp and in mosquito ditch excavation which is estimated at two cents per foot as compared with three cents in last year's estimate.

It appears from the above and from the plans, estimates and methods described in the statement submitted by the Commission for work to be carried on in 1922, that careful study has been given by the Commission to the relative amounts which should be apportioned to the various phases of the work in such a manner as to produce the best results. While no attempt has been made to analyze in detail the items of cost, a comparison with previous work here and elsewhere indicates that the work for 1922 has been efficiently planned and reasonably estimated upon by the Commission and warrants your approval.

It was, therefore, recommended that the estimates, plans and methods as submitted covering the year 1922 be approved in accordance with the provisions of section 412 of chapter 408 of the Laws of 1916, and that they be forwarded to the Board of Supervisors of Nassau county.

Respectfully submitted,

C. A. HOLMQUIST,
Director, Division of Sanitation.

ALBANY, N. Y., *September* 17, 1921.

PALISADES INTERSTATE PARK

At the request of the Public Health Council the Engineering Division (Division of Sanitation) made a sanitary survey of the Palisades Interstate Park. This park consisting of some 36,000 acres is located between the Palisades along the Hudson river and the Ramapo mountains, partly in the State of New York and partly in the State of New Jersey. It is controlled by a Commission appointed by the Governors of the two states and supported by appropriations from the states and by private contributions.

Some 60 camps are maintained throughout the park which, together with boats, camp equipment and other facilities are rented to acceptable and responsible organizations. In addition permits for individual camps are issued. Each of these permanent camps is supplied with water and sewerage facilities. The sanitary survey of the Park includes detailed studies and inspections of the water supply and the method of disposal of the sewage at each camp. An investigation was also made of the bathing beaches maintained by the Commission along the Hudson river in the State of New Jersey.

The reports upon the sanitary survey and the investigation of the bathing beaches of the Palisades Interstate Park follow.

An investigation of the Palisades Interstate Park with especial reference to the water supply, sewage disposal and general sanitary conditions of the various camps, parks and bathing beaches maintained throughout the park, was made by Mr. Earl Devendorf, assistant engineer in this Department, during the period extending from August 10 to September 4, 1920.

This investigation was made at the request of the public health council, and our engineer was assisted by Mr. William A. Welch, chief engineer of the Palisades Interstate Park Commission, who detailed an assistant to accompany and guide the engineer on the investigation throughout the extensive park area.

The Palisades Interstate Park was created in 1900 by the States of New York and New Jersey for the purpose of preserving the Palisades of the Hudson. The park is controlled by an unpaid commission appointed by the Governors of the two States and supported by appropriations from the two States and by private contributions. There are 1,000 acres in New Jersey extending for 12 miles along the Hudson river, 550 acres in Blauvelt tract west of Nyack, 780 acres in the Hook mountain-Rockland lake section and 33,708 acres in the Bear mountain-Harriman section.

The park has been developed by a force operated under the supervision of the Commission and organized under separate departments, having a general manager. Roads have been built, paths and trails cleared, lakes formed. docks and beaches constructed, camp buildings, ice houses, pavilions, lunch rooms and restaurants erected and steamer and automobile transportation furnished.

At the time of the inspection the Commission had a large force of men engaged in the construction of roads, camps, etc., in the undeveloped section of the park lands mainly lying in the Bear mountain-Harriman section. Another large force was employed in directing the activities of the camps which are rented, annually to acceptable and responsible organizations. All camps have police protection, telephone service and medical attention. In addition permits for individual camps are issued upon application for camping at Alpine, N. J., Hook mountain, Bear mountain and Brooks lake.

As a matter of ease in presenting the various facts, in order to simplify this report, the investigation of the bathing beaches maintained by the Commission along the Hudson river in the State of New Jersey will be described in detail in a separate report and only the camps maintained by the Commission in the State of New York will be discussed here in detail.

The geological formation of the whole region of the Bear mountain-Harriman section consists of gneiss with many intrusions of lava. The Palisades, which extend for 30 miles along the west bank of the river as a cliff several hundred feet high are intrusions of lava forming sills which are underlain with sandstone and formerly were covered with sedimentary strata. With sub-strata of this character, fissures may occur and the source of any water supplies derived from springs and wells located in this region is indeterminate. The ground water flow tributary to the wells and springs may come from a long distance and be subject to pollution although they may apparently be satisfactorily located.

It is mainly for the above reasons that the water supplies derived from wells and springs at the various camps have been viewed with suspicion. Furthermore, with the very large summer population, consisting mainly of young boys and girls and numbering at times over 75,000 which roam promiscuously over the entire park area, any supply derived from a stream, pond or spring is subject to the accidental, incidental or chance pollution from such a population. The probability of carriers being present in such a large population is very great and for the above reasons it was thought advisable that an endeavor should be made to have each water supply serve as large a number of camps as possible in order that all of the smaller supplies may be abandoned.

Before reaching definite conclusions or making recommendations with regard to some of the camps it was thought desirable to have a conference with the park authorities in order to receive the benefit of a knowledge of any local conditions that would have a bearing upon the matter. Accordingly a conference was held on February 25, 1921, with the chief engineer of the Park Commission and the practical questions arising at the various camps discussed and definite plans and procedures decided upon with reference to the numerous questions arising with respect to the many improvements in the sanitary facilities and surroundings at the various camps and beaches existing or planned for the future throughout the park area. The detailed recommendations and proposed changes are embodied in the memoranda on the various camps and only a summary of the more important of the proposed improvements will be discussed here under the headings of water supply, sewage disposal and general sanitary conditions.

Water Supplies

At Bear mountain the present water supply is derived by pumping from a spring which is subject to pollution. It is proposed to develop a new supply in conjunction with the United States government reservation on Iona island by constructing an impounding reservoir on a small brook at a point below Doodletown and about one mile west of Iona island. The consumption required by the government at Iona island is said to be about 50,000 gallons per 24 hours while that at Bear mountain is at times over 500,000 gallons per 24 hours. The flow at this brook is said to be sufficient to supply this quantity for about 8 or 9 months during the year but that for the remainder of the year it is almost dry. The available storage of the proposed reservoir is to be 60,000,000 gallons which will provide an ample supply under the above conditions. A filter plant is to be installed and the filtered water is to be sterilized before being pumped to either Bear mountain or Iona island for consumption. It would be advisable to provide the filters and a chlorination plant in duplicate in order that a continuous supply of treated water be furnished at all times.

The sanitary conditions on the watershed should be carefully watched in order that no insanitary conditions may exist on the watershed and if necessary the park authorities should apply to this Department for the enactment of rules and regulations for the sanitary protection of the water supply. If these precautions are taken and the purification plant is properly designed and efficiently operated an ample supply of water of a satisfactory sanitary quality may be had at all times.

For the tent camps at Bear mountain a new water supply should be developed or the camp abandoned.

The spring at BM-17, used as a main source of supply, should be properly protected and the auxiliary spring should be abandoned.

The dug well at Brooks lake should be abandoned and the drilled well should be properly protected from pollution.

The Negro Fresh Air Camp building was in poor repair and the sanitary conditions surrounding the camp were very unsatisfactory. For these reasons it would appear advisable to abandon this camp.

At the caretaker's cottage in the Queensboro lake section the spring should be protected from pollution. At the Y. W. C. A. camp the spring supply should be retained and the well supply abandoned. No water from Queensboro brook should be pumped for use unless first receiving treatment through a properly operated filter plant.

The spring for the Camp No. C-4, located on the northwesterly side of Lake Tiorati should be properly protected in accordance with the various recommendations embodied in the accompanying memoranda. The same is true for the spring at Camp No. C-2. These spring supplies may be retained since they can be properly protected from pollution and also since no other camps are planned to be erected on this side of the lake. On the southerly and southeasterly shore of the lake, however, it is planned to erect camps during the coming summer to accommodate some 1,000 campers and eventually it is expected that 2,000 to 2,500 campers will be accommodated here. For a water supply it is planned to filter and chlorinate the lake water having an intake placed in about 30 feet of water at the northerly end of the lake and away from the camps. It is believed that if the purification plant is properly designed and efficiently operated that this will give an ample and satisfactory sanitary supply of water. In this connection the units of the purification plant should be installed in duplicate in order that there may be no interruption in the operation due to a breakdown.

For the camps at Lake Kanawauke the spring pond supply should be used exclusively and the various wells and springs abandoned, except that during the winter season when the spring pond supply is not available, certain of the wells may be used if properly protected from pollution, as pointed out in the memoranda on the various camps. The spring pond supply should be protected from pollution in accordance with the various recommendations embodied in the memorandum on Camp No. K-1, and treated by a properly designed and efficiently operated filter and chlorination plant. In this connection it would be advisable to install all the units of the purification plant in duplicate to guard against any interruption in treatment of the supply due to a breakdown.

At Lake Stahahe the spring at Camp No. 6 should be abandoned. The Green pond supply should be protected by fencing the watershed of the pond as well as the side of the mountain above the distributing reservoir to the outlet of the supply pipe and subjected to treatment by a properly operated filter plant which should be provided in duplicate units.

At Twin lakes the use of Lower Twin lake water for washing purposes should be discontinued and the spring pond supply used for all purposes. The spring pond supply only should be used at the camps on both Upper and Lower Twin lakes and should be sterilized by means of liquid chlorine. For this purpose duplicate apparatus should be installed to guard against any interruption in the service. The house and chicken yard located near the pond should be removed. A tight fence provided with a locked gate should be erected at a sufficient distance from the edge of the pond to insure against pollution of the supply from any of the campers and drainage ditches should be dug to prevent the entrance of surface water. The well at Lower Twin lake No. 4 and the spring at Upper Twin lake No. 7 should be abandoned.

For the proposed Cohasset lake camps a supply may be developed by impounding the waters of Sure Bridge pond brook and forming a reservoir at a point above and to the south of the lake site. This reservoir should be protected from pollution by fencing the area around the reservoir and constructing drainage ditches. The supply should also be subjected to purification through a properly designed and operated filter plant, for which the units should be furnished in duplicate.

At Summit lake it is proposed to abandon the present camp and construct another camp on the lake for which a well supply is to be developed. As pointed out in the memoranda on this camp this supply will, if properly protected, furnish a water of satisfactory sanitary quality. Until the present camp is abandoned, however, the recommendations embodied in the report should be carried out.

For the Rockland lake camp the well should be properly protected as outlined in the memorandum on this camp.

At Hook mountain beach another source of water supply should be developed and the present well supply abandoned. For this purpose it is suggested that the Nyack public water supply be furnished by extending a pipe line to the beach.

At Blauvelt the sanitary surroundings of the well used to supply the caretaker's house should be carefully watched and the use of the Spring Valley Water company supply continued for the main supply.

At Hazard, Englewood, Bloomers and Alpine beaches the use of the springs and wells should be discontinued and the Hackensack Water company supply used by running a water pipe line to convenient points along the beaches from the main which is located on the top of the cliff and parallel with the beaches.

At Forest View the well at the tent camps should be abandoned and the spring protected. The other springs should also be properly protected from pollution in accordance with the recommendations embodied in the memoranda.

Sewage Disposal

The matter of sewage disposal appeared to be satisfactorily cared for by the park authorities, who have an organization formed for the purpose of looking after the toilets at the various camps and beaches. The modified Kaustine toilets, constructed by the park authorities, appeared to be operating satisfactorily. It would appear desirable, however, to provide a deflector in the toilets provided for the men, in order to deflect the urine into the toilet and prevent the wetting of the side and floor in front of the toilet seat. From the testimony of the authorities in charge of the camps and from the observations made at the time of the inspection of the various camps, it would appear that the odor of the chemical used, which is mainly sodium hydroxide, tends to drive the flies away. Very few, if any, flies were observed at any of the Kaustine toilets.

The data covering the operation of the Kaustine toilets for the season 1920, as furnished by the park commission, show that the quantity of chemical used varied from .042 to .068 pounds of Kaustine per camper per day and that the material removed amounted to approximately 10 gallons per pound of Kaustine used. It appears that the most important element is the proper charging and frequent cleaning of the vaults or containers.

There were several instances in which privies were found in an insanitary condition at the time of the inspection. These conditions have been covered in the memoranda and recommendations made for improvement.

With respect to capacity there were several places where the capacity appeared insufficient and others where the capacity was questionable. These have been pointed out in the memoranda and in the latter cases it has been recommended that the authorities make careful observations of the conditions of operation and if occasion warrants increase the capacity. Several instances were observed and noted in the memoranda on the various camps in which the toilet wastes were being disposed of in an unsatisfactory manner and in some instances, it has been recommended that the toilet be moved and the pit used for receiving the toilet wastes be cleaned, the sides and bottom sterilized with lime and filled with earth. Too great care cannot be taken in disposing of the toilet wastes in order that they may cause no nuisance or pollute any water supply.

General Sanitary Conditions

The general sanitary conditions of the grounds surrounding the various camps and beaches as well as the park property in general were found to be satisfactory with the exception of a very few camps. In each case it has been recommended that the garbage and refuse be collected daily and burned in order that no insanitary conditions may arise on the grounds surrounding the camps or beaches.

In conclusion it was recommended that copies of this report, together with the memoranda on the sanitary conditions of the various camps, be sent to the Palisades Park Commission and that the recommendations embodied in the report and the memoranda be carried out at an early date.

A reinspection was made of the sanitary conditions at the bathing beaches maintained by the Palisades Interstate Park Commission on the west shore of the Hudson river opposite New York City and Yonkers, with special reference to the matter of water supply and sewage disposal at these beaches.

This inspection was made on August 31, 1920, at the request of the Public Health Council by Mr. Earl Devendorf, assistant engineer of this Department in company with Mr. H. V. Dickenson, resident engineer of the Palisades Park Commission.

Previous inspections were made in 1918 and 1919 and the reports thereon may be found in the Annual Reports of the State Department for the respective years.

The general conditions of the beaches are practically the same as outlined in the former report and these features will not be reported at this time.

Hazard Beach

Hazard Beach is situated at the foot of the Palisades at Fort Lee, N. J., nearly opposite Fort Washington, New York City. It is reached from New York City by ferry from 158th street and by private launches and canoes and from various points in New Jerey by automobiles and trolley to Fort Lee. It is estimated that the population at the beach during the summer open season from July 1st to September 1st ranges from 5,000 to 15,000 persons on Sundays, holidays and week ends. On other days the population varies greatly from a few hundred to the maximum stated above. The general conditions remain practically the same as stated in the former report. with the exception that the Commission is filling in the land north of the beach along the river to form a playground.

A building containing a bath house, equipped with shower baths and toilet facilities, and a pavilion is still in practically the same condition as at the time of the previous inspection. For the men there are 13 Kaustine chemical closets and 5 five feet urinals and 9 lavoratories. For the women there are 22 Kaustine chemical closets and 10 lavoratories. The contents of the iron Kaustine tanks are pumped out about once every 2 weeks and carted away to a point about one-half mile above the beach where the ground is being filled in as a proposed playground. It was stated that the material is covered immediately and that no insanitary conditions have arisen. In addition there were at the time two old wooden privies located along the beach north of the pavilion. These were in poor sanitary condition having no screens provided and no covers for the seats. These privies should be removed and either sanitary privies with removable containers and properly protected against flies should be installed or some other suitable provision should be made to replace these privies in accordance with the previous recommendations.

The water supply for drinking and shower baths at this beach is furnished largely by the Hackensack water supply. The water for drinking purposes is piped to the well, the conditions surrounding which remain practically as those described in the previous report, with the exception that the gate has been moved to a point at the entrance of the tunnel in order to prevent unauthorized persons from entering the tunnel and causing any possible pollution of the water. It was stated that the Hackensack water is used for about six weeks' period during the summer and only on days when the attendance is very large and the spring flow is not sufficient to furnish the required amount of water. This well, as stated previously was originally excavated and blasted out of solid rock consisting of red and grey sand stone to a depth of about 400 feet below the ground surface. It would appear that this well might at times be subject to pollution from the populated district lying west of the river in as much as the sub-strata is entirely rock and may be fissured. It would, therefore, appear advisable to discontinue the use of this well and take the supply for drinking purposes entirely from the Hackensack water supply.

The drilled well formerly used for drinking purposes and located some 1,100 feet north of the boat landing has been abandoned and the pump removed.

At the time of the inspection a sample of water was collected from the pump at the spring at Hazard Beach and sent to the Division of Laboratories and Research for analyses, the results of which are given in the appended table.

The results of these analyses show a water having rather high nitrates and chlorine contents. The results of the bacteriological examination show a very high total bacterial count with the presence of organisms of the B. coli type in inoculations as small as one-tenth cc., indicating the presence of active contamination at the time of the inspection.

Bloomer Beach

The bathing beach at this point is situated one-half mile north of the Englewood end of the Dykeman Street ferry. The beach is reached from New York City by this ferry and by the river in private boats. It is estimated that on Sundays, holidays and week ends the maximum attendance reaches as high as 20,000.

There are 2 two-story pavilions used as shelters and gathering places at this beach. These pavilions are of rustic construction and are located approximately one-half mile apart. In addition there are two small bath houses which are constructed at this beach, one for the use of the men and the other for the use of the women. At the time of the inspection the sanitary conditions of these buildings appeared to be satisfactory.

In the southerly pavilion there are 2 toilet rooms; 1 for women, which is equipped with 3 flush closets and 3 lavoratories, and 1 for men, which is equipped with 2 flush closets, 2 wash basins and one 6-foot urinal. The sewage from these toilet fixtures is discharged into the Hudson river opposite the pavilion about one-half mile south of the bathing beach. It was recommended in a previous report that this discharge of sewage in the proximity of the bathing beach, which may at high tide be carried to the bathers, should be discontinued and the sewage disposed of in some other suitable manner.

At the northerly pavilion two 8-hole Kaustine toilets have been erected in place of the two wooden privies which were formerly used. The wastes

from these toilets are removed at frequent intervals and deposited ir
cesspool nearby. It would appear that at times of maximum attendance
toilet facilities at this beach are apt to be overtaxed. A careful stu
should be made by the authorities in charge of the park in order to det
mine if this condition really exists and if so to provide additional to
facilities.

Near the Englewood ferry there is a spring located approximately
feet back from the river and at the foot of a steep slope. The flow fr
this spring is led through a 1½-inch overflow pipe. The spring is not
situated with regard to the sanitary surroundings in view of the la
number of bathers having access to the vicinity of the spring, and
in view of the fact that the substrata is composed largely of rock wh
may be fissured and allow pollution to enter the ground water sup
from which the spring is derived at a very great distance. It would app
advisable, therefore, to abandon the use of this spring as a source of dri
ing water supply.

Another spring known as the South Spring at Bloomer Beach cons
of a small concrete basin provided with a pump located 15 feet below
away from the basin for drawing the water. The area surrounding
spring, however, has not been fenced and is open to the bathers, who n
possibly cause pollution of the ground within the vicinity of the spri
The spring furthermore is located at a distance of only 100 feet from
of the Kaustine toilets and pits provided for disposal of the toilet was
This may also constitute a source of pollution for the spring supply.

The North Spring at Bloomer Beach which was used as a source of dr
ing water supply by the bathers is located about 1,000 feet above the no
erly pavilion and some 15 feet away from the river. The spring has b
developed by the construction of a concrete covered box provided with a p
to which is connected the pump for drawing water from the spring. T
pump is located at the edge of the river some 15 feet away from the spr
basin. The water surface of the river at high tide is approximately 3
below the ground elevation. The spring basin is covered with about 1 f
of earth. The area surrounding the basin has not been fenced to prev
bathers from coming in the vicinity of the spring, which may give rise
opportunities of pollution of the supply.

Another source of drinking water supply at this beach is the spring kn
as the Powder House Spring. This spring, located north of Bloomer Be
is provided with a wooden curb and cover on which the pump is loca
directly over the spring. The spring is said to be 8 feet in depth.
fact that the cover is of wood may give rise to some pollution from the wa
water flowing into the spring. It would appear advisable therefore to ab
don the use of these springs as sources of drinking water supplies and
use the Hackensack Water Company supply by tapping the company m
located at the top of the cliff above the beach.

At the time of the inspection samples of water were collected from
various springs and sent to the Division of Laboratories and Research
analyses.

The results of the analysis of a sample collected from the Englew
spring show a high chlorine and nitrate content. The results of the bact
logical examination show a very high total bacterial count and the pres
of organisms of the B. coli type in inoculations as small as one-tenth
indicating the presence of active contamination at the time of the inspect

The results of the analysis of the sample collected from the South sp
at Bloomer Beach show a moderate nitrate content with a high chlor
The results of the bacteriological examination show a high total bacte
count and the presence of organisms of the B. coli type in all of the inoc
tions examined, indicating the presence of active contamination at the t
of the inspection.

The results of the examination of the sample collected from the No
Spring at Bloomers Beach show a moderately hard water having no c
and only a slight turbidity. The figures for nitrogen in its various fo
are moderate and the oxygen consumed content is also low. The figures

chlorine, however, are rather high. The results of the bacteriological examination show a high total bacterial count and presence of organisms of the B. coli type in all of the 10 cc. and 1 cc. inoculations examined, indicating that the supply was receiving some active contamination at the time of the inspection.

The results of the analysis of the sample collected from the Powder House spring show a high chlorine and nitrate content. The results of the bacteriological examination show a high total bacterial count with the presence of organisms of the B. coli type in all of the inoculations examined, indicating that the supply was actively contaminated at the time of the inspection.

Alpine Beach

This bathing beach is situated at Alpine, N. J., opposite Yonkers, and is reached by means of a ferry. The maximum population visiting this bathing beach on Sundays, holidays and week ends is estimated as varying from 250 to 1,500 persons per day. At this beach there are two small bath houses, 1 for men and 1 for women. There are three 2-hole Kaustine toilets, 2 of which are provided with 5-foot urinals. These toilets are pumped out every 2 weeks and the wastes disposed of by burial on a hill located about ¼ of a mile below the beach. It is said that the wastes are covered over with earth immediately and no insanitary conditions have arisen due to this practice. Care should be taken, however, to carefully observe the conditions of this dump in order to prevent the occurrence of any insanitary conditions that might arise from the material not being properly covered or disposed of.

As pointed out above in the discussion on the capacity of the toilets at Bloomers Beach, it would appear that the capacity of the toilets at Alpine Beach are deficient at times of maximum attendance. The authorities in charge of the beach, however, should make careful observations to ascertain if this condition exists and, if so, to remedy same by increasing the number of toilets at this beach.

At this beach a spring supply is used as a source of drinking water, the spring being located on the side of a steep slope just below the roadway paralleling the river. The spring is apparently covered over. The ground surrounding the spring is very steep and the spring is said to come from sandstone underlying trap rock. The water from the spring flows to a wooden tank located below the spring which is 8 feet in diameter and 6 feet in height and has a capacity of approximately 2,250 gallons. It would appear that this spring is open to pollution from possible surface wash from the roadway and the land above the roadway over which the bathers have free access. Furthermore, the area surrounding the spring had not been fenced to prevent the bathers from coming in the vicinity of the spring, thus possibly causing pollution of the ground around the spring.

Another source of supply at this beach comes from a spring located about ⅛ of a mile above the beach. The spring has been developed by constructing a basin 10 x 12 feet in cross-connection and 8 feet in depth. The pump house has been constructed adjacent to this spring and is equipped with a 3-horsepower gasoline and plunger pump. The spring itself is located approximately 75 feet from and 25 feet above the river. No fence has been erected around the spring to prevent bathers from coming in the vicinity of the spring. The water is pumped to a 15,000 gallon covered concrete reservoir located on the slope, from which the water flows by gravity to the 4 taps located on the beach. It is said that they use approximately 6,000 to 8,000 gallons of water per week. The reservoir is located some 300 feet from and 100 feet above the river.

At the time of the inspection samples of water were collected from the 2 springs and sent to the Division of Laboratories and Research for analyses.

In view of the unfavorable conditions surrounding one of these springs and the availability of the Hackensack Water Company supply from a main located on the top of the cliff above the beach it would appear advisable to carry this supply to the beach to be used exclusively for drinking purposes.

The results of the analysis of the Alpine Beach spring show a moderately hard water having very slight color and no turbidity. The figures for nitrogen in its various forms are moderate, with the exception of the nitrate content which is very high, as is also the oxygen consumed content. The figure for chlorine is also rather high. The results of the bacteriological examination show a very high total bacterial count with the presence of organisms of the B. coli type in the majority of the 10 cc. and some of the 1 cc. inoculations examined, indicating the presence of some active contamination at the time of the inspection.

The results of the analysis of the sample of water collected from the Alpine Beach spring, located ¼ of a mile above the dock, show a high total bacterial count and the absence of organisms of the B. coli type in all of the inoculations examined, indicating the absence of any active contamination.

Forest View Beach

This bathing beach is situated along the western bank of the Hudson river and about 1 mile south of and opposite to Hastings. This beach is mainly reached by boats from the river and the maximum attendance is said to be about 2,500 on Sundays, week ends and holidays during the season. A dock has been constructed along the river and a large pavilion constructed for the use of the bathers. The shores of the beach were free from rubbish and were in a general sanitary condition. All the garbage, paper and refuse deposited on the shores by visitors, not only at this beach but at all the other beaches, are collected and burned daily by the park employees.

At this camp there are two 6-hole wooden dug vault privies provided for the use of the bathers. These privies are located near the springs used as a source of public drinking water supply and may, under changing hydrostatic conditions of the ground water flow, cause pollution of the drinking water supply and, furthermore, are not very satisfactory for use under the conditions existing at the beach. New toilets of a more sanitary type should be constructed with either a removable container or other satisfactory means of disposing of the wastes and so located that the drinking water supply may not be polluted. Care should be taken, furthermore, by the authorities in charge of the camp to observe the operating conditions of the toilets in order to determine the number of toilets to be provided, for if sufficient toilet facilities are not provided insanitary conditions may arise at times of maximum attendance.

At a point about ½ mile below Forest View there are 175 to 225 tents located on the slope above the river. The average population of these tents, which are used by week end parties, is approximately 500. There are 2 dug vault privies provided for the use of these campers. One is a 2-hole and the other a 4-hole privy. These privies are said to be cleaned each week and the excreta covered with earth each day. Both privies are situated 75 feet from and 20 feet above the spring supply. It is said that these 2 privies are to be replaced by a 4-hole and an 8-hole concrete Kaustine toilet. The pits should be cleaned, the sides and bottoms sterilised with chloride of lime and filled with earth. Care should be taken in the removal of the toilet wastes in order that the water supply may not be polluted. The spring from which the drinking water supply at these tent camps is derived is located about 6 feet above the camps and is covered with concrete. Care should be taken to fence an area surrounding the springs in order to prevent the campers from causing any possible pollution of the supply.

The drinking water supply at Forest View is derived principally from a dug well provided with a loose stone wall 10 feet square and covered with a wooden cover. The pump is located some 30 feet away from the well for drawing the water. The ground surrounding the well is not fenced to prevent the campers or bathers from coming in the vicinity of the well and causing any possible pollution. The well is located approximately 20 feet from and at a slightly higher elevation than the river. The land to the west of the well rises very abruptly. There is another spring used as a source of drinking water supply and located approximately 200 feet north of the above well. This spring is also constructed in a similar manner to the above-described spring and is provided with a pump. Both of these spring supplies may be open to possible pollution from surface water entering the stone wall as well as from the privy which is located midway between the 2 springs and at approximately the same elevation. At a distance of about half way between Forest View bathing beach and the tent camps located to the south there is a well located in rock 15 feet deep in which the water was, at the time of the inspection, only 3 feet in depth. Water is pumped from this well by means of a pump located 10 feet from and above the well. This well, however, is open at the top and is subject to pollution from the campers who may come within the vicinity of the well. This well should be abandoned as a source of drinking water supply and the well covered up.

At the time of the inspection samples of water were collected and sent to the Division of Laboratories and Research for analyses. The results of the analysis of the sample collected from the spring at the tent camp opposite Greystone show a very high total bacterial count which may be in part due to the multiplication of water bacteria as the result of delay in transit since the samples were 4 days in reaching the laboratory. Organisms of the B. coli type were found in 1 of the 10 cc. inoculations examined, indicating the presence of a small amount of active contamination at the time of the inspection.

The results of the analysis of the sample collected from the North spring at Forest View Beach show a high total bacterial count with the presence of organisms of the B. coli type in all of the 10 cc. and some of the 1 cc. inoculations examined, indicating that the supply was receiving some active contamination at the time of the inspection.

The results of the analysis of a sample collected from the Middle spring at Forest View Beach show a moderately hard water having little color or turbidity. The figures for nitrogen in its various forms are moderate with the exception of the nitrate content which is a trifle high. The oxygen consumed content is moderate and the chlorine content is rather high. The results of the bacteriological examination show the presence of organisms of the B. coli type in all of the 10 cc. and 1 cc. inoculations examined, indicating that the supply was receiving some active contamination at the time of the inspection.

The results of the analysis of the sample collected from the well below Forest View show a moderately hard water having some color and little turbidity. The figures for nitrogen in the form of free ammonia is very high as is also those for nitrites. The chlorine is also high. The results of the bacteriological examination show a high total bacterial count with the presence of organisms of the B. coli type in inoculations as small as 1/10 cc., indicating that the supply was actively contaminated at the time of the inspection.

As a result of the above investigation the following conclusions were drawn in a report dated February 24, 1921:

Hazard Beach.

1. That at Hazard Beach the privies situated north of the beach have not been removed or replaced with a more suitable type of toilet in accordance with the recommendations of the former report.

2. That at Hazard Beach the gate in the tunnel leading to the well had been moved to the entrance of the tunnel in accordance with our previous recommendations.

3. That the driven well at Hazard Beach has been abandoned and the pump removed.

Bloomers Beach.

4. That the sewage from the toilets in the 2 pavilions at Bloomers Beach is still being discharged into the river and the recommendations of the former report for disposing of the sewage in some other way have not as yet been carried out.

5. That the privies at Bloomers Beach have been replaced with Kaustine toilets but at times of maximum attendance the sewage facilities are apparently still insufficient to accommodate the large number of bathers.

6. That the springs used as sources of drinking water supply at Bloomers Beach are all subject to opportunities for pollution and are not of a satisfactory sanitary quality.

Alpine Beach.

7. That the spring water supply derived from Alpine Beach was not of a satisfactory sanitary quality.

8. That the drinking water supply derived from the spring located ⅛ of a mile north of Alpine Beach was of a satisfactory sanitary quality although the spring was at the time of the inspection open to opportunity for contamination from the large number of bathers having free access to the vicinity of the spring.

9. That the toilet facilities at this beach are apparently inadequate to accommodate the number of bathers visiting this beach, especially on week ends, Sundays and holidays.

Forest View.

10. That the sewerage facilities are not of a satisfactory sanitary type and are apparently inadequate to accommodate the number of bathers visiting this beach on week ends and holidays.

11. That the North spring used as a source of drinking water supply at Forest View Beach is not properly protected from pollution.

12. That the Middle spring used as a source of drinking water supply at Forest View Beach is not properly protected from pollution.

13. That the well at the tent camps below Forest View Beach is open to opportunities for serious contamination.

14. That the spring at the camps at Greystone was apparently of a satisfactory sanitary quality.

The following recommendations were made:

Hazard Beach.

1. That the authorities in charge of the beach should, in accordance with our previous recommendations, take every precaution in disposing of the toilet wastes in order that no objectionable conditions may arise or that the wastes may not be washed into the river in such a manner as to cause pollution of the river water in which the people bathe.

2. That the privies north of the beach should be abandoned and other toilet facilities provided with a removable container or other satisfactory type.

3. That, in view of the possibility of pollution reaching the ground water flow tributary to the spring supply, this source of drinking water should be abandoned and only the water of the Hackensack Water Company used for this purpose.

4. That the driven well which has already been abandoned, in accordance with our previous recommendations, should not be used.

Bloomers Beach.

5. That, in accordance with the recommendations of the previous report, the sewage from the toilets in the two pavilions at Bloomer Beach should be disposed of by some other means than dumping into the Hudson river at a point liable to cause pollution of the water in which the bathers swim.

6. That the authorities in charge of the beach should make a careful study of the toilet facilities in order to determine the necessary additions to be made to the present facilities and add whatever toilet units are found to be necessary.

'hat, since the springs used as a source of drinking water supply
oomers Beach are all subject to opportunities for pollution and
an unsatisfactory sanitary quality, they should be abandoned
nother supply of satisfactory sanitary quality obtained such as
ackensack water supply, which is available through a pipe line
located on the cliff above the beach.

Beach.

'hat the Alpine Beach spring used as a source of drinking water
should be abandoned and another source of supply of satisfactory
ry quality obtained such as the Hackensack water supply, which
ilable through the existence of a pipe line on the top of the cliff,
f and above the beach.

'hat the authorities in charge of the beach should enclose the
round and continue careful supervision of the sanitary surround-
f the spring located ⅛ of a mile west of Alpine Beach in order
o insanitary conditions may arise to cause pollution of the drink-
ater supply from this spring.

That the authorities in charge of the beach should make a care-
udy of the toilet facilities with reference to the number of visitors
ek ends, Sundays and holidays, in order to determine the number
litional toilet units to install, and these facilities should be in-
l at as early a date as possible in order that, at these periods of
num attendance no insanitary conditions may arise due to the in-
ate toilet facilities.

View.

That the present privies at Forest View Beach should be aban-
the pits cleaned and the sides and bottom sterilized with chloride
e and filled with earth, in order that there may be no possibility of
ion of the drinking water supply from these sources.

That additional toilet facilities should be provided with remov-
ontainers, or of a more satisfactory sanitary type, and so located
cause no possible pollution of the drinking water sources.

That both the North and Middle springs used as drinking water
es should be protected by:

(a) Fencing an area around the springs.

(b) Construction of drainage ditches to divert surface wash in
ne vicinity of the springs.

(c) Repairing the stone walls of the spring basins to prevent
ollution of the supply by the entrance of surface wash.

That the authorities in charge of the beach should continue care-
pervision of the conditions surrounding the springs opposite Grey-
in order that no insanitary conditions may arise to cause pollution
supply.

That the well used as a source of drinking water supply at the
amps should be covered and abandoned as a source of drinking
supply.

That the authorities in charge of the benches should carefully
ise the operation of the toilets, in order that there might arise
anitary conditions due to improper operation or infrequent clean-
the toilets.

That in disposing of the toilet wastes the authorities should exer-
treme caution in order that these toilet wastes may not be depos-
t any point liable to cause pollution of the various drinking
supplies.

That the authorities in charge of the camp should continue the
t practice of daily collecting and disposing of all refuse, in order
no insanitary conditions may arise along the beaches from this

INVESTIGATION OF COUNTY FAIR GROUNDS

An investigation was made by the Engineering Division during 1920 of the sanitary condition of all county fair grounds in this State with special reference to water supply, sewerage and sewage disposal, garbage and refuse disposal, and the adequacy of the toilet facilities at these fairs. A number of fair grounds were visited while the fairs were in progress and the actual operating conditions were observed. The report upon the investigation follows.

The following report on the sanitary conditions at the county fairs of the State of New York was based on inspections of the grounds, made by Mr. Charles T. Male, sanitary inspector of this Department, between July 1 and September 30, 1920:

General

During these months all the fair grounds in the State, excepting that at Troupsburg, Steuben county, which was omitted on account of lack of time, were visited, and special studies made at 10 of the fairs while they were in progress. Particular attention was given in this investigation to the matter of water supply, sewage disposal and waste disposal.

According to the records of the Department of Farms and Markets there were, not including the State Fair at Syracuse, 81 agricultural fairs held in the State during the year 1920. Two societies which have previously held fairs, The Rensselaer County Agricultural and Horticultural Society and the Southern Steuben County Agricultural Society, did not hold fairs during 1920. The total attendance at the fairs is estimated at 1,800,000, the attendance at the individual fairs varying from 1,500 at New City, Rockland county, to 140,000 at Rochester, Monroe county. The fairs generally extend over a period of about four days during which the attendance is not equally divided, the number of persons visiting a fair on the day of maximum attendance being about 43 per cent of the total number visiting the fair during the days on which it is open. The attendance on the maximum days averaged about 9,500, varying from 500 to 25,000. It is this attendance, about 80 per cent of which is on the ground at the same time, that is of the greatest importance in a study of the sanitary conditions and requirements at the fairs.

Attendance

The figures for the attendance at the different fairs, together with certain information regarding water supplies and toilet facilities, is given in the appended tables Nos. I and II. In a few places it was not possible to secure reliable information on the attendance and the figures in these cases are therefore, necessarily omitted. Detailed observations of the attendance to determine the variation during the day, the ratio of the number of persons on the ground at one time to the total attendance for the day and the proportion of men, women and children were made at the fairs at Altamont, Oneonta and Nassau, the results of which are shown on the attached diagrams and in table No. III. A study of these diagrams and tables indicates that in general the attendance increases at a nearly uniform rate from the opening of the fairs in the morning until about 2:30 p. m., then at a less rapid rate until 3:30 p. m., at which time the number of persons on the grounds begins to decrease. Weather conditions and special attractions, of course, influence the rate and time at which persons arrive at the fair. The maximum number of persons on the ground at one time was found to be from 70 to 90 per cent of the total attendance for the day. Of the total attendance from 53 to 60 per cent, an average of 55.2 per cent were men. No attempt was made to obtain the percentage of children since for the purposes of this investigation it did not seem necessary. All children of such age that they would probably use the women's toilets were counted under women and children. A few observations made at one of the fairs indicated that about 8 or 10 per cent of the total attendance were children.

Water Supply

The water supplies for use at the fairs are generally obtained from the public supply of the nearby cities and villages, from wells on the fair grounds or from both sources. A study of table I indicates that 57 per cent of the fairs representing 70 per cent of the total attendance obtain their supply exclusively from public municipal supplies, 28 per cent of the fairs representing 20 per cent of the total attendance obtain their water exclusively from wells and that 14 per cent of the fairs representing 10 per cent of the attendance use both the public and municipal supplies and wells. The quality of the water obtained from the public supplies from the nearby cities and villages, is usually of safe quality for human consumption. The method of distributing the water is, however, in many cases, not entirely satisfactory. The water is generally piped to hydrants conveniently located about the grounds varying from 2 to 50 in number at each fair. The ratio of the number of hydrants to the number of persons visiting the fair on the day of maximum attendance varies from 1 hydrant to 160 persons to 1 hydrant to 10,000 persons, and averages about 1 hydrant to each 1,200 persons, the average being greater at the smaller fairs than at the larger ones. The ratio at fairs having an attendance of under 5,000 people, varies from 1 to 150 to 1 to 2,500 averaging about 700 persons per tap, and at those having an attendance of over 5,000 people from 1 to 250 to 1 to 10,000, about 1,400 persons per tap. The difference is apparently due largely to the necessity of securing satisfactory distribution for small fairs. Very few fairs are equipped with sanitary drinking fountains and at fewer still are individual paper cups provided. At Avon, Cortland, Cuba, Middletown, Mineola, Perry, Rochester and Watertown and a few other places, some sanitary drinking fountains are provided varying in number from 1 to 6, and at Binghamton and Batavia, paper cups are provided. At most of the fairs, however, the common drinking cup is used or the people use such vessels that they may have handy, and at some places water is obtained by dipping from large vessels. The use of the common drinking cup at public fairs needs little comment. It has for many years been considered a menace to the public health and its use in public places is prohibited by Regulation 3 of Chapter VII of the Sanitary Code. The practice of dipping water from large unprotected vessels and of carrying water from the taps to the places where it is to be used for drinking in open vessels, is an unsatisfactory procedure as it affords opportunity for contamination. It would seem desirable that all fairs should be provided with sanitary drinking fountains of a satisfactory type conveniently located or that paper cups should be provided at all the taps accessible to the public. In either case the use of common drinking cups should not be permitted. The number of drinking fountains or taps of drinking water that should be provided, of course, varies with the attendance. Observations made at the fairs seemed to indicate that at least 1 sanitary drinking fountain or tap supplied with paper cups should be provided for each 500 persons visiting the fair on a day of maximum attendance except that in order to secure proper distribution every fair should have at least eight fountains or taps provided with cups. Precautions should be taken to locate the fountains or taps at convenient points so as to reduce the probability of water being taken for drinking purposes from unsatisfactory sources. This is particularly true in cases where taps are provided for watering stock, for it is found that those handling and inspecting the animals are apt to take water from those taps in any vessel that may be convenient. Part of the fountains should be so arranged that they may be reached by children.

At those fairs where water from city or village supplies is not available the drinking water is generally obtained from dug wells, drilled wells and in a few cases from springs. The number of wells provided varies from 1 to 8 and averages about 2½ per fair or 1 for each 3,000 persons visiting the fair on the day of maximum attendance. These sources are in a few cases satisfactorily protected from pollution but in many cases very little attention has apparently been given to the location or protection of the wells. In most cases the wells are shallow, either dug or driven and equipped with pitcher or suction pumps. Little precaution has generally been taken to prevent the entrance of the waste water from the pumps or surface wash which with large numbers of persons passing and repassing over the ground nearby will undoubtedly carry considerable pollution. Many of the wells are located close to privies and stables from which pollution undoubtedly reaches them. At Batavia, Ballston Spa., Hamburg and a few other places, those in charge of the fairs have developed the wells or other sources of supply so as to form private water systems from which water is distributed to hydrants the same as the water from the municipal sources is distributed. This procedure is generally to be recommended and should be carefully considered at all fairs, for it allows of a better protection of the supply than when the wells are used directly and necessarily located in places where large numbers of persons congregate. Where funds are not available for the installation of a general system it will probably be possible to develop and protect a well and pump the water from it by means of a hand pump, wind mill or gasoline engine to a small elevated tank from which it may be distributed to hydrants. In all such cases the sources should be carefully protected from pollution and the water distributed with the same precautions as are used for municipal supplies.

Where it is impossible to secure water from a public supply or to develop, at present, a private system as suggested, the conditions can in most cases, be materially improved at small expense. If dug, the walls of the wells should be made watertight to a depth of at least 8 feet to prevent the entrance of water from the upper strata which is generally subject to pollution. The ground around the wells for a distance of 10 or 20 feet should be graded to drain away from the wells and concrete platforms fitted with tight covers and sloped from the wells and extending 4 to 8 feet on all sides should be provided to prevent the entrance of foreign material. A tight fence should enclose an area at least 20 feet in diameter around each well to prevent trespassing and the consequent pollution of the soil, and the pumps should be located outside of these enclosures. Troughs or drains should also be provided to receive waste water from the pumps and conduct it to a considerable distance from the wells. If driven or deep wells are used it will, of course, in most cases be necessary to locate the pumps over the wells. In such cases the casings should be absolutely tight, the ground around the wells for a distance of 10 or 20 feet should be graded to drain away from the wells, watertight concrete platforms sloped from the wells and extending 4 to 8 feet on all sides should be provided to prevent water spilled near the wells from seeping into the ground near them, and troughs or drains should be arranged to receive waste water and conduct it to a considerable distance from the wells.

The distance by which wells and privies should be separated depends, of course, somewhat on the nature of the soil. A coarse gravel and rock or clay with crevices or openings will permit the passage of pollution for a considerable distance, while a fine sand will generally render polluting matter inert in a relatively short distance. No wells should be located within 300 feet of a privy or stable if the water is to be used for drinking or culinary purposes and precautions should also be taken to see that the drainage from the vicinity of the privies and stables does not flow toward the wells. It will, of course, generally be considered necessary to locate one or more wells near the stables for watering the stock. When this is done every precaution should be taken to prevent water from these wells being used for drinking purposes. This can be accomplished by arranging the pumps so that the spouts discharge under water in the troughs or in some other manner so that it will be inconvenient or impossible to obtain water from them for drinking.

Where both village supplies and well water are used at present the wells should be abandoned for drinking and culinary purposes and arrangements made for the satisfactory distribution of the village water.

Toilet Facilities

The toilet facilities at the fairs vary considerably in both type and condition. Of the 81 fairs, 5 fairs, or 6 per cent of the total number, are equipped with flush closets only. The attendance at these fairs is about 10 per cent of the total attendance. Thirteen of the fairs, or 17 per cent of the total number, are provided with both flush closets and privies. At 63 of the fairs, or 77 per cent of the total number, however, privies only are provided. Less than half the toilets were in satisfactory sanitary condition. The number of fixtures provided at each fair is given in the appended Table No. 11. From a study of this table it appears that the number of facilities varies from less than 1 seat per 1,000 attendance at Watkins to 1 seat for every 53 persons attending the fair on the day of maximum attendance at Plattsburg. The figures for all the fairs, regardless of whether equipped with flush closets or privies, indicate that on the average, 1 seat is provided for about every 250 persons visiting the fairs on the days of maximum attendance. These facilities are provided as follows: One seat for men for every 555 attendance, or 1.8 seats per 1,000 attendance; 1 urinal (considering 2 feet of urinal trough as one urinal) for every 950 men, or 1.05 urinals per 1,000 attendance, and 1 seat for women for every 435 attendance, or 2.3 seats per 1,000 attendance. On the basis of the number of men and women on the ground at one time at the fairs this is 1 seat per 250 men, or 4 seats per 1,000 men; 1 urinal per 410 men, or 2.4 per 1,000 men, and 1 seat per 160 women, or 6.3 seats per 1,000 women.

Special studies were made at Altamont, Oneonta, Nassau and Hamburg to determine the number of toilets that are necessary for a given attendance. Curves showing the rate of use at these toilets at the fairs on certain days are plotted on the attendance curve sheets attached and the results have been briefly summarized in Table No. IV. It is immediately apparent on examining the data that the rate of use of the toilets is not directly proportional to the number of persons on the grounds but is governed largely by the attractions at the fairs, the people apparently visiting the toilets between events of interest. It is also apparent that while the use of the toilets increases as the attendance increases, it does not follow the increase to its highest point, the rate of use of the toilets being no greater during the two or three hours while the crowd is largest than when only about 75 per cent is on the grounds. This is probably due to the fact that there are more interesting events for the period of maximum attendance and also to the fact that those who visit the fairs for only a short period in the afternoon do not use the toilets. The maximum rate of use of the toilets observed, excepting at Hamburg which will be considered later, was 41 men and 74 women and children per hour for every 1,000 persons attending the fair on that day. The average maximum rate at Altamont, Oneonta and Nassau for every 1,000 persons attending the fair was 40 men per hour and 66 women and children per hour. The average maximum rate for one full hour, however, was a little less than this, being about 25 men per hour and 51 women and children per hour. The fact that these figures show that the women and children use the toilets more than twice as frequently as men at most fairs is a matter which requires some attention. The figures are difficult to explain unless, as seems probable, the men avoid using the toilets if any other convenient place is available. This fact is important for, with the improvement in the sanitary condition of the toilets and their location at more convenient points, it is probable that the rate of use for the men would increase. A study of the conditions at Hamburg, where new and sanitary flush toilets have recently been provided and where, during the period of observation, the rain kept the people under shelter to a large extent, seemed to support this conclusion, for it was found that even allowing for the fact that there was a greater proportion of men on the grounds than usual, the men used the toilets more frequently than women.

The number of persons that one toilet seat will accommodate per hour is dependent to some extent upon the arrangement of the seats and compartments, the convenience of ingress and egress and the condition of the toilets. In general, however, it was found that on the average one seat would accommodate about 25 women per hour. With the maximum rate of use of the toilets of 74 women per hour per 1,000 total attendance this would require the provision of approximately 3 seats per 1,000 attendance, a number somewhat greater than the average of 2.3 now provided at the fairs, but lower than the number provided at 11 or 13 per cent of the fairs. Considering the fact that when the condition of the toilets is improved as it should be, the rate of use will probably increase considerably and that the distribution of the toilets will make it impossible for them all to be used at the maximum rate at the same time, and it would seem that at least 4 seats should be provided for women for each 1,000 persons attending the fairs on the day of maximum attendance.

The determination of the number of fixtures which should be provided for the men is a more complex problem. Observations indicate that on the average one seat will accommodate about 15 men per hour and one urinal about 40 men per hour, and that about 15 or 20 out of every 100 men visiting the toilets use the seats and the remainder the urinals. Figuring from this basis and the fact that a maximum of 41 men use the toilets per hour at the fairs, excepting Hamburg, where observations were made, it would seem necessary to provide only about 0.53 of a seat and 0.80 of urinal for each 1,000 persons visiting the fair on the day of maximum attendance. As noted previously, the observations at Hamburg indicate that under certain conditions the use of the toilets by the men may be more than doubled while the use by women is only slightly affected. The maximum rate of use by the men at Hamburg was 111 per hour per 1,000 attendance, or 195 per cent greater than at any other fair, while that for women and children was 76 or only 2.7 per cent greater than the maximum figure for the other fairs. Using this figure which will probably be more nearly correct, when toilets of a satisfactory type are provided and maintained in proper condition, it would seem necessary to provide about 1.5 seat and 2.2 urinal per 1,000 persons attending the fair on the day of maximum attendance.

Another factor not previously discussed which affects the use of the men's toilets more than the women's must also be considered before determining the number of toilets needed. The crowds move with the attractions from one part of the grounds to another. It was often found that, for example, while races were being held the toilets near the tracks were used to capacity while those in other parts of the grounds were practically empty, the reverse being true when no racing or track events were going on. It is at once apparent, therefore, that the number of men's toilets, if they are distributed about the grounds at convenient points, as they should be, to prevent the commission of nuisance and the pollution of the ground, must provide a greater number of fixtures than that just mentioned. The necessary increase is difficult to figure accurately but from such observations as could be made it seemed advisable that 2 seats and 3 urinals should be provided for each 1,000 attendance at the fairs on the day of maximum attendance, figures slightly different from 1.8 and 1.05 the average now at the fairs, but in accordance with the generally observed condition that the ratio of urinals to seats was not great enough at most of the fairs.

At the smaller fairs it is probable that more toilet fixtures will be required for both men and women than the above figures indicate in order to secure satisfactory distribution. In no case should the number of fixtures be less than that required for 4,000 attendance according to the above figures.

The types of toilets used at the fairs depend to a large extent, on local conditions. Where conditions permit and funds are available it seems desirable that flush closets should be provided as has been done at Hamburg, Rochester, Malone, Ogdensburg and Walton and partially at Dunkirk, Plattsburg, Cortland, Westport, Batavia, Lowville, Cobleskill, Hornell and other places where the privies are being gradually replaced by flush closets. Such closets where provided should be of the standard siphon type provided with separate flushing tanks of at least 4 gallons capacity or suitable flush valves. The closets should be set at least 3 feet on centers. The urinals should be of corresponding type and should preferably be flushed automatically as experience shows that individual flushing cannot be relied upon. The floors should be of concrete or other impervious material and the lower 6 inches of the wall should be of similar material. The building should be of ample size and well lighted and ventilated. Experience seems to indicate that toilet rooms should contain about 250 cubic feet of air space per fixture and when compartments are used that they should be 3 feet wide and 4 feet or 4 feet 6 inches deep. There should be at least 2 square feet of window space per fixture and never less than 8 feet square. The doors and windows and ventilators should, of course, be screened and the screen doors so constructed as to stand rough usage. Double swing doors are usually most satisfactory. Toilet paper should be provided or difficulty will probably be experienced due to stoppage in the sewer lines.

The disposal of the sewage from the flush toilets is a problem which varies so with different conditions that it is difficult to make any suggestions that will cover all cases. Where city or village sewers can be reached the solution is, of course, simple, and where large streams or other bodies of water are available the sewage may in most cases be discharged into such water after proper treatment. Where grounds are located inland and away from streams more complete treatment will, of course, be required, the type of plant depending upon local conditions. In any case the plans for the disposal of the sewage should be prepared by a competent engineer and must, according to law, be approved by this Department.

While flush toilets are, without question, the most desirable form for use at fairs, it will undoubtedly be necessary for most fairs to continue the use of privies, provided either with earth vaults or with removable containers. The former type will probably be found best suited to the condition at the majority of the fairs and is the type now generally in use. It was found, however, that at most fairs little attention was apparently given to the construction or maintenance of the privy buildings. The buildings were found to be improperly located in many cases, the construction was in general not entirely satisfactory and few were maintained in sanitary condition. Practically none were completely screened and fly-tight, although many were located near places where food and drinks were sold. It would seem, therefore, that more attention should be given to these buildings.

Where earth vault privies are provided they should obviously be located so as to preclude the possibility of any drainage from them reaching any well. The vaults should be generally 4 or 5 feet deep and about 4 feet wide, the length, of course, depending on the number of seats. The sides of the excavation should be tight sheeted with well braced planks to prevent caving and provide means for making a tight fly-proof joint with the privy building. Well fitted doors may be provided, if desired, to afford access to the vaults for cleaning. The privy building itself should be tight boarded and provided with a well fitted self-closing door. The floor area should be at least 18 square feet for each seat and ventilation should be provided by openings having an area of not less than 1 square foot for each seat. The vault may be ventilated by a shaft from it extending above the roof. All ventilating openings should be covered with wire screens of not less than 14 meshes to the inch. Frequently sprinkling the contents of the vault with dry earth or lime will generally tend to reduce the odors. The contents of the vault should not be allowed to reach within 18 inches of the surface of the ground before the vault is cleaned and the contents removed and disposed of by burying in some remote place. Where the privies are small and sufficient area is available it is sometimes possible to move the building to another site and fill the old vault without cleaning it. Where this is done the vault should be deep and an ample covering of earth provided over the matter deposited in it.

Where privies provided with removable containers are used the same precaution regarding location, size, fly-tightness, screening and ventilation should be observed as in the case of the earth vault privy. The doors to the container compartments should fit well and the containers, preferably of metal, should be watertight. The containers should be changed and their contents disposed of in a sanitary manner before there is any danger of overflowing.

The urinals provided in connection with the privies are at present of several different types; in some cases they consist of a rail and a shallow ditch, in some the top board of the seats has been removed, in others wooden or metal troughs are provided which drain to privy vaults or to cesspools. It would seem desirable that wherever possible the urinal troughs should be of galvanized iron or preferably of enameled iron or, if slabs are used, of slate or other impervious material and drain to leaching cesspools of suitable size so located as not to endanger the water in any well. The walls back of the urinals should be waterproof and the floors under them for a distance of 3 feet from the wall should be of concrete or other impervious material and arranged to drain to the cesspool. The urinals should be flushed out frequently. The same precaution in regard to area, ventilation and screening should be observed as in the case of privies.

In general all toilets, whether flush closets or privies, should be located at convenient points and kept in sanitary condition so as to reduce the probability of the pollution of the ground, and of sufficient capacity to accommodate the number of persons apt to congregate in that part of the grounds. Where wells are used toilet buildings should be located as far as possible from them and precaution should always be taken to see that no food is handled or distributed within 100 or, preferably, a greater distance from any toilet.

Garbage and Rubbish Disposal

The disposal of the garbage and rubbish at the fairs does not generally present a very difficult problem and the fact that the fairs are open for only a few days makes it improbable that the accumulation of refuse will ordinarily cause a nuisance. It would seem advisable, however, that some provision should be made for caring for and disposing of the refuse. At some fairs it is collected in cans and removed and disposed of daily by burning, burying or other method, while at others no provision whatever is made for its collection or disposal. It would seem desirable that galvanized iron cans of suitable size, equipped with covers, be provided at the kitchens and other places where food is prepared or dispensed, to receive the wastes, and that similar cans be provided at suitable points about the grounds in which persons may deposit rubbish, and that these cans be collected and their contents disposed of daily in a sanitary manner, either by burning or burying.

Conclusions and Recommendations

Since the conditions at the different fairs vary widely it is impossible to make detailed recommendations for improvements that will apply to all or even most of them, and for this reason individual memorandums have been prepared, briefly outlining the condition at each fair and making suggestions for improving its sanitary condition. It seems, however, that certain general recommendations will apply to a greater or less extent to many fairs and we therefore recommend that those in charge of the different fairs give attention to the following insofar as they apply to the fairs in which they are interested.

In regard to water supplies:

1. Water for drinking and culinary purposes should, wherever possible, be taken from the mains of nearby municipalities.

2. Where water from a municipal supply is not available a private system from a well protected source should, if possible, be developed and piped to the different parts of the grounds.

3. Where it is necessary to use wells:

(a) All dug wells and all driven or drilled wells where possible, should be so arranged and developed that the pump will be at least 15 feet from the well, and the area around the well for a distance of not less than 10 feet on all sides enclosed with a tight fence and trespassing on the area prohibited.

(b) All wells should be located at least 300 feet from any stable or privy and, if possible, on higher ground.

(c) The walls or casings of all wells should be watertight for a distance of at least 8 feet below the surface of the ground.

(d) The ground around the wells for a distance of at least 10 feet in all directions should be graded to turn water away from them.

(e) A tight concrete platform sloped away from the well and extending at least 5 feet from it in every direction, should be provided over each well.

(f) Troughs and drains should be provided to receive waste water and conduct it to a considerable distance from the wells.

(g) If wells are located near stables for convenience in watering stock, the pumps should be arranged by having the spouts discharge under water in the troughs or other means to make it impossible to obtain water for drinking and every precaution be taken to prevent the water from these wells from being used for drinking or culinary purposes.

4. Where water is distributed through a system of pipes at least one sanitary drinking fountain or tap should be provided for each 500 persons visiting the fair on the day of maximum attendance. Such taps or fountains should be located at convenient points and some arranged so that they may be used by children. In no case should less than eight be provided.

5. The transportation of water in open vessels and the practice of dipping water from such vessels for drinking purposes should be prohibited.

6. Common drinking cups should not be provided and their use should be prohibited.

In regard to the toilet facilities and the disposal of the sewage:

7. Whenever possible toilets should be equipped with flush closets and urinals.

8. Where it is not possible to provide closets and urinals, well constructed privies and urinals of the type described in the body of this report for such conditions, should be provided.

9. Toilets should be located at convenient points so as to provide ample facilities for crowds that may collect in any part of the grounds, but should never be located within 300 feet of any well used as a source of water supply for drinking or culinary purposes or within 100 feet of any place where food is handled or dispensed.

10. All toilet buildings should be fly-proof and all openings, doors, windows and ventilators in such building should be properly screened with wire mesh with not fewer than 14 wires to an inch.

11. All toilets should be maintained in clean and sanitary condition.

12. Where flush toilets are provided:

(a) There should be not less than 250 cubic feet of space and at least 2 square feet of openable window area per fixture.

(b) The closets should be set at least 3 feet on centers and urinals not less than 2½ feet on centers.

(c) The floor and first six inches of the walls should be of concrete or other impervious material and the floors should be properly drained.

(d) An ample supply of toilet paper should be provided.

(e) The sewage from the toilets should be discharged into a public sewer or disposed of in a disposal plant designed by an experienced sanitary engineer and approved by the State Department of Health.

13. Where privies are provided:

(a) At least 25 square feet of floor space and not less than 1 square foot of ventilator opening should be provided per seat.

(b) If of the earth vault type, the contents of the vault should never be allowed to rise within 18 inches of the surface of the ground before the vault is cleaned or the privy moved and the vault filled.

(c) If of the container type, the containers should be replaced and the contents disposed of before there is danger of their overflowing.

(d) The contents of the vaults or containers should be disposed of by burying in some remote place.

(e) Urinals should be of galvanized iron, enameled iron or other impervious material arranged to drain to a cesspool.

(f) The wall back of the urinals should be of impervious material and the floor under the urinals for a width of 3 feet should be of concrete or other impervious material and drained to the same cesspool.

(g) Urinals should be flushed out and dry earth or lime be sprinkled into the vaults or containers at frequent intervals.

14. The number of fixtures provided should be as follows:

(a) Not less than 2 seats and 3 urinals for men for each 1,000 persons visiting the fair on the day of maximum attendance.

(b) Not less than 4 seats for women for each 1,000 persons visiting the fair on the day of maximum attendance.

(c) When urinal troughs are provided, not less than 2 feet of trough and preferably 2½ feet should be considered as one urinal.

(d) Not less than enough seats and urinals to allow of proper distribution about the grounds regardless of the attendance and in no case less than enough for 4,000 people.

15. For the purpose of collecting the garbage and refuse, galvanized iron cans, equipped with suitable covers, should be provided at all kitchens and places where food is handled and distributed and at convenient points about the grounds. These cans should be collected daily and the contents disposed of by burying or burning.

USE OF TOILETS AT CERTAIN COUNTY FAIRS, 1920

Table No. IV

LOCATION	Date	Attendance	MAXIMUM NUMBER USING TOILETS PER HOUR PER 1,000 ATTENDANCE			
			MAXIMUM RATE		MAXIMUM FOR ONE HOUR	
			Men	Women and children	Men	Women and children
Altamont	Sept. 22, 1920	6,373	29	58	19	56
Oneonta	Sept. 23, 1920	13,758	28	47	27	38
Nassau	Sept. 16, 1920	3,400	23	74	20	65
Nassau	Sept. 17, 1920	2,657	41	72	34	44
Average	....	....	30	63	25	51
Hamburg	Oct. 1, 1920	3,580	111	76	103	67

Observations at Nassau indicated that the ratio of the use of seats to the use of urinals at that fair was about 15:100.

At Hamburg, where it rained almost continuously during the fair, the number using the toilets was over twice the average for the other fairs.

REFUSE DISPOSAL

A number of investigations were made during 1921 by this Division, of public nuisances created by the improper disposal of municipal refuse, including a number of nuisances caused by inadequate or improperly operated incinerator plants. In each case a report was prepared and transmitted to the local authorities in which the results of the investigation were set forth and recommendations made as to the proper treatment and disposal of refuse. Under the provisions of chapter 247 of the Laws of 1921 plans and specifications for a garbage and rubbish incinerator for the village of Port Chester were submitted to this Department for approval before construction. These plans and specifications were approved on August 16, 1921. The report on the examination of the plans and specifications follows:

Hermann M. Biggs, M. D., *State Commissioner of Health:*

I wish to submit the following report upon the examination of plans and specifications for the proposed garbage and rubbish incinerator for the village of Port Chester, Westchester county, N. Y., submitted to this Department for approval in accordance with the provisions of Chapter 247 of the Laws of 1921, on July 12, 1921.

General

Port Chester has a population of about 17,000 persons and is situated on Long Island Sound and the Byram river in the eastern part of Westchester county some 20 miles from New York City. The Byram river forms the boundary line between the states of New York and Connecticut at this point. The village has a public water supply derived from Pipen and Horseneck brooks and a public sewerage system and disposal works whose effluent discharged into Long Island Sound.

Site

The site upon which it is planned to locate the incinerator plant is adjacent to the present public dump on the southerly side of Fox Island road, at a point opposite and about 100 feet beyond the site of the village sewage disposal works. It is situated on the southerly shore of the neck of the peninsula which lies between Byram river and Port Chester harbor. The site provided is about 250 feet wide and has a total depth of about 750 feet of which about 1/10 lies between the road and the present harbor shore. There is one factory near the proposed plant. The nearest residences are reported to be on the opposite side of the Byram river in the state of Connecticut, at a distance of about 1,000 feet.

Incinerator Plant

According to the plans and specifications submitted the incinerator plant is to consist of 3 separately specified items, viz: a building, an incinerator furnace and a smoke stack. It is stated that the stack is built on rock and that a portion of the building is to be on rock and the remainder on heavy piling. No attempt has been made by us to pass upon the foundation or on the stability of the different structures.

The plant is designed to consume 30 tons of refuse per 24 hours. According to data furnished by the designing engineer the maximum amount of refuse, including garbage and rubbish collected a day is about 6 tons. This does not include ashes which are to be disposed of separately. It appears, therefore, that the incinerator need be operated only 8 hours per day without exceeding its capacity for a considerable time in the future.

Building.— The building to house the incinerator is to be a concrete structure about 30 feet square, designed with two floors or stories connected by a stairway and covered by a slag roof. The upper or charging floor is to be of reinforced concrete and is to be at an elevation of 24 or about level with Fox Island road, with which it is connected with a short driveway passing across the center of the floor. The entrance and exit are protected by rolling lift steel doors. The charging floor is to be provided with a rectangular opening about 3 feet by 4 feet, guarded by double doors arranged for dumping refuse into the incinerator furnace below. A toilet on an elevated platform and chute for boxes are also provided on this floor.

The basement or incinerator floor is at elevation 11.5. On one side of this room is shown an exterior smoke breeching and on another side is to be provided an exterior coal bin, each 5 feet in width. This floor or room will contain the incinerator, combustion chamber, smoke breechings and forced draft fan. In this room will also be located a boiler feed pump, a small engine to drive the forced draft fan and a preheater by means of which the air draft is to be heated by being passed through a chamber containing pipes through which the hot fumes from the incinerator pass on their way to the stack.

Incinerator furnace.— The incinerator shown by the plans is of the medium temperature Decaric type and consists of a steel water jacket furnace equipped with a water-cooled basket-grate composed of heavy pipe, which branch from a central header and connect with the water space of the furnace. This grate, upon which the refuse falls from the charging floor above the furnace, is suspended above a 5-foot by 8-foot shaking grate, upon which coal is burned when the furnace is started and coal and refuse or refuse alone is burned under forced draft after the furnace is in full operation. Steam for driving the fan and supplying forced draft is generated in the furnace so that it will act as a steam boiler.

Combustion chamber.— This chamber is to be located adjacent to the end of the incinerator furnace and is to be constructed of steel plate with fire brick lining. A checker wall is to be placed near the entrance to the chamber to serve as a screen, and hot air is to be introduced near this point. This chamber is intended to act as a combustion chamber to burn the unconsumed gases given off from the incinerator. It will also act as a dust chamber inasmuch as the velocity of the gases will be checked, due to the enlarged cross section. Clean-out doors are to be provided in the sides of this chamber through which the dust may be removed.

Preheater.— This heater is to be installed at the lower end of the combustion chamber and consists of numerous steel tubes through which the gases of combustion are to pass. The air from the fan is to be forced through the preheater around the outside of the tubes, through which the gases pass for the purpose of heating the forced draft used in the incinerator and combustion chamber. Beyond this preheater is the smoke breeching. Provisions are made, however, for by-passing the preheater and passing the gases of combustion direct to the stack.

Stack.— The plans and specifications show that it is planned to build a perforated radial brick chimney 100 feet in total height. It is to have a minimum diameter of 3½ feet, and is to be lined with fire brick to a height of 20 feet. To this height it is to be octagonal in form and above this point it is to be cylindrical. The stack is to be located about 5 feet from the smoke breeching and between the latter and the road. A lightning conductor and interior ladder is to be provided. The chimney or stack of the size and character designed, while none too capacious, if properly constructed should be sufficient to meet the present needs of the type of incinerator plant required for the village.

Method of Operation

As stated above it is planned to operate the incinerator only 8 hours a day at first or until the amount of refuse collected is so increased as to require longer periods of operation. In starting the incinerator a coal fire will be built on the shaking grate of the incinerator or, if a banked fire is maintained during the night, additional coal will be added. This fire will be maintained under natural draft until the furnace is heated and sufficient steam is generated to drive the fan which supplies the forced draft before any refuse is discharged into the incinerator. The fan is then to be put into operation, forcing the air through the preheater, where it will be heated before it is applied to the duct under the fire grates in the form of a forced draft.

When the required temperature is obtained in the furnace, which should not be less than 1200° or 1400° F., the refuse is to be discharged into the incinerator from charging floor above through a hopper provided with automatic closing doors, which should tend to prevent the gases of combustion from escaping into the charging room under the forced draft of the incinerator or cold air from entering the furnace. The refuse falls onto the water-cooled basket-grate of the incinerator suspended above the shaking or fire grate, to prevent the wet garbage from falling onto and choking the fire below. Vertical water-cooled pipes extend up along the inside of the incinerator to prevent wet material from coming in contact with the cold sides of the water-jacketed furnace. The fire from the coal and from the ignited dried material will pass up through and around the refuse drying and igniting it. The unconsumed gases and gases of combustion will then pass into the combustion chamber where additional air will be added and where a complete combustion of the gases should be effected, provided a sufficiently high temperature and a proper mixture of air is maintained. This chamber as well as the breeching, should act as dust chambers and prevent the escape of dust into and from the stack. The efficiency of the plant and freedom from objectionable odors will depend largely upon the completeness of the combustion in the incinerator and combustion chamber. In order to obtain complete combustion an adequate supply of air should be provided, the temperature should be maintained at not less than 1200° or 1400° Fahrenheit and no garbage should be discharged into the incinerator until this temperature is obtained. Pyrometers should be provided in order to enable the operator to determine the temperature in the incinerator and combustion chambers.

It appears usual to provide an induced draft fan in addition to a force draft fan in order to prevent the escape of gases into the room above the incinerator during the charging process. It would seem well to so construct the plant as to readily permit of installing an induced draft fan if found necessary or desirable.

Trial Run

The specifications stipulate that, upon the completion of the incineration plant, the contractor shall operate the plant continuously for a period of 48 hours. The refuse to be incinerated or destroyed at the trial run is to consist of 65 per cent garbage by weight, 33 per cent rubbish by weight and 2 per cent dead animals by weight. A variation of 10 per cent above or below the proportion of garbage, rubbish and dead animals specified is to be allowed in the test.

It is noted in the addenda specifications that the garbage used during the trial run shall have a moisture content of not greater than 80 per cent. The minimum moisture content of the garbage should also be stated or stipulated in specifications.

The specifications also stipulate among other things that the successful bidder for the construction of the incinerator shall make the following guarantees:

1. That the plant, under normal operation will cause no nuisance from the escape of obnoxious odors, smoke or grease from either the building or the stack.
2. That the refuse shall be incinerated to a mineral ash free from organic material.

I am of the opinion that the bond of the contractor should be so drawn as to insure the results guaranteed above.

Conclusions and Recommendations

In conclusion I would state that, in my opinion, if the above guarantees are fully carried out and if the proposed incinerator plant is properly constructed and operated with care and efficiency, it should satisfactorily care for the garbage and rubbish of the village for a reasonable period in the future. Although the type of furnace or incinerator shown has lower temperatures when in operation than some other types, I believe that it can be so operated as to obtain complete combustion and prevent the creation of a nuisance. If some other type of incinerator is adopted, detailed plans for such incinerator should be submitted to this Department for approval before it is installed.

In view of the results of our examination of the plans and specifications and after a careful consideration of the essential features of design and the local and general requirements for the proper methods of the disposal of garbage and rubbish in the village of Port Chester, I would recommend that these plans and specifications be approved.

Respectfully submitted

C. A. HOLMQUIST

Director, Division of Sanitation

ALBANY, N. Y., *August* 15, 1921

On September 30, 1921, amended plans providing for modification of the incinerator building were approved.

FORTY-SECOND ANNUAL REPORT OF THE STATE DEPARTMENT OF HEALTH

April 28, 1924

MATTHIAS NICOLL, JR., M. D., *State Commissioner of Health,*
Albany, N. Y.:

SIR.—It is my privilege to transmit herewith the annual report of the Division of Vital Statistics for the calendar year 1921, which is the forty-second report of the State Department of Health on the registration of births, marriages, and deaths, and its thirty-seventh annual compilation of statistics of same.

There has been a delay of a number of months in the final publication of this report owing to a misunderstanding on the part of another State Department concerning the appropriation for its printing. Immediately upon discovery of this, steps were taken to expedite the report as rapidly as possible.

You will find the contents of this report comparable in practically all important respects with the standard tables presented in this Division's report for 1920, except that the sequence of the tables has been improved and there have been added several important tables of marriage statistics for the year 1920.

Deserving of special mention are Miss Ella H. Porter, who supervised the compilation of the primary data for births and deaths, including the derivative data; Mr. Paris R. Eastman, who had charge of the mechanical tabulations, gave important aid in the design of the birth and marriage tables and who supervised the entire compilation of the latter, and Miss Carolyn A. Boudo, who prepared the introductory comment and reviewed the final proofs.

We are also indebted to the office of the Attorney-General for their ever willing and courteous aid in the legal technicalities of registration procedure.

Most of all, I feel personally obligated and grateful to you and our late Commissioner, Dr. Hermann M. Biggs, for your generous policy toward the development of our statistical reports and your constant encouragement.

Very truly yours

OTTO R. EICHEL

Director

REVIEW OF VITAL STATISTICS FOR THE YEAR

Population

The population of New York State, estimated as of July was 10,543.105; that of New York City, 5,751,859; and t of the State, 4,791,246. These estimates were computed simple arithmetic method using the State Enumeration o and the U. S. Census of 1920 for the rest of the State, a U. S. Censuses of 1910 and 1920 for New York City. Tl mates for the rest of the State and all its subdivisions from 1921 were revised using the State Enumeration of 1915 a U. S. Censuses of 1910 and 1920 and the rates presented historical tables are based upon these new estimates.

Births

The number of live births registered in the State nu 240,210 — a rate of 22.8 per 1,000 estimated population number registered in 1920 was 235,460 with a rate of 22. increase in 1921 was very slight, only 4,750 births compar an increase of 9,191 in 1920 over 1919. The sudden incr 1920 was to be expected as a natural reaction after the w the rate for 1921 indicates that there is already a slowing this increase.

Marriages

In 1921 there were registered in this State 101,437 ma 9,843 less than in 1920. The rate was 19.2 persons marr thousand total population, while in 1920 it was 21.3. Tl rate in 1920 was to be expected after the termination of t and the rate for 1921 indicates a return to the normal rate At the end of this report will be found extensive tables, ing many correlation tables, on marriage statistics for tl 1920. They show the color, age, conjugal condition, r of bride and groom, month of marriage, relative ages of ea These tables supplement those already published for tl 1919 and for the years 1916–1918 combined.

Deaths

The outstanding feature of the mortality for 1921 was t low general death rate. For the whole State the rate w representing the very lowest death rate on record for th The 1920 rate of 13.8 was lower than any previously r rate and the drop to 12.3 was indeed most exceptiona number of deaths was 130,110, the smallest number on since 1904 when the population of the State was only abo million. If the average rate of 1913–1917, 15.2, had p there would have been 160,255 deaths in this year, or 30,1 than actually occurred.

The death rates for New York City and for the rest of the State for 1921 were likewise the lowest on record, New York City's being 11.2, and that for the rest of the State, 13.7. When these rates were adjusted for the age and sex composition of the population according to the Standard Million of England and Wales, the following results were obtained:—

AREA	CRUDE RATES			ADJUSTED RATES		
	Male	Female	Total	Male	Female	Total
New York State	12.8	11.8	12.3	12.4	11.6	12.0
New York City	11.8	10.5	11.2	12.9	12.0	12.4
Rest of State	14.0	13.3	13.7	11.9	11.4	11.7

The specific age rates by sex for New York City and the rest of the State are noteworthy:—

AGES	DEATH RATES PER 1,000 POPULATION AT EACH AGE GROUP			
	MALES		FEMALES	
	New York City	Rest of State	New York City	Rest of State
0–4 years	26.375	27.179	21.537	22.280
5–9 years	3.378	3.348	2.657	2.705
10–14 years	2.420	2.431	2.058	2.055
15–19 years	3.293	3.562	2.817	3.015
20–24 years	4.137	4.267	3.590	4.292
25–34 years	4.707	4.804	4.371	4.880
35–44 years	7.892	7.036	6.709	6.342
45–54 years	15.041	11.484	12.414	10.838
55–64 years	31.462	23.978	28.029	21.824
65–74 years	65.620	55.043	59.815	50 297
75 years and over	130.974	140.008	125.960	132.927

It will be seen that in general the rates under 35 years are slightly *lower* in New York City than in the rest of the State; that the rates from 35–74 years are *higher* in New York City than in the rest of the State; and that those for 75 years and over are *lower* for New York City than for the rest of the State.

The ten leading causes of death in 1921 were as follows:—

	Number deaths
Organic heart disease and endocarditis	23,0
Pneumonia and influenza	11,4
Cancer	11,1
Tuberculosis (all forms)	10,7
Nephritis and Bright's disease	9,4
Accidents	7,1
Cerebral hemorrhage and apoplexy	7,1
Congenital debility and malformations	6,9
Arteriosclerosis	4,6
Diarrhea and enteritis (under 2 years)	3,9

A comparison of the mortality from various diseases in 19
with that in 1921 shows that the decrease in 1921 was due chief
to a lower mortality for the diseases of the respiratory syste
The very low mortality in the winter months of 1921 bears th
out. Applying the death rate of 1920, 13.8, to the population
New York State in 1921, we find that there would have be
145,495 deaths this year instead of 130,110 — a saving of 15,3
lives. The death rate from influenza, pneumonia, bronchitis, a
pulmonary tuberculosis combined in 1920 was 336.8 per 100,0
population; in 1921, 208.4. If the 1920 death rate for this grou
had prevailed in 1921 there would have occurred 35,509 deat
instead of 21,975, a saving of 13,534 lives or 88% of the tot
saved.

The very low death rates in New York State in 1921 were lik
wise manifest throughout the whole U. S. Registration Area a
in certain foreign countries. The Registrar-General of Engla
and Wales reported the lowest general death rate ever record
and attributed the fact to the favorable meteorological conditio
which prevailed, the year 1921 as a whole being the warmest a
driest (i.e., of lowest rainfall) for many years.

Infant Mortality

The number of deaths under 1 year of age in 1921 for t
entire State was 18,070, 2,256 less than in 1920 and the rate
proportion to each 1,000 live births was 75 as compared wi

of 86 for the preceding year. This was the lowest rate on l for the State and is an index of the progress that is being in health work. The reduction occurred chiefly among the ing diseases:

	NUMBER OF DEATHS UNDER 1 YEAR	
	1921	1920
and enteritis	3,354	3,947
	106	306
g cough	417	520
ia (all forms)	2,209	2,910
is	390	672
	97	404

rrhea and enteritis (under 2 years), a very important cause ath among infants, resulted in 3,952 deaths in 1921 correing to a mortality of 37.5 per 100,000 population, whereas 20 it caused 4,662 deaths with a rate of 44.7. Of the 3,952 s in 1921, 3,354 were under *one* year of age, making diarrhea nteritis responsible for 18.6 per cent of the infant mortality s year. The death rate from this cause should be based upon umber of births each year to give a more accurate index of tions. In comparing New York City with the rest of the this is especially true. There were 1,702 deaths under one from this disease in New York City and 1,652 in the rest of tate, but the rate in each per 1,000 live births was 12.7 in York City and 15.6 in the rest of the State. The death rate 00,000 population from this cause has been declining rapidly, ing been as high as 123.1 in 1900.

	Deaths	Rate per 100,000 population
1917 (annual average)	6,154	62.8
	5,122	50.1
	4,191	40.6
	4,662	44.7
	3,952	37.5

genital debility and malformations caused 6,959 deaths in corresponding to a rate of 66.0 per 100,000 population. Of tal 6,959 deaths, 6,853 occurred in the *first* year of life — , therefore, comprised 37.9 per cent of the total infant mor- of the State. Of the total 6,853 deaths under one from these conditions, 3,391 occurred in New York City and 3,462 the rest of the State. In proportion to 1,000 live births in ea area, the rates were 25.3 for New York City and 32.7 for t rest of the State.

Year	Deaths	Rate p 100,0 populat
1913–1917 (annual average)	8,178	83
1918	7,995	78
1919	7,135	69
1920	7,115	68
1921	6,959	66

Important Causes of Death

Typhoid fever. The number of deaths allocated to this dise in 1921 was 377, only 6 more than in 1920. The annual avera number of deaths in 1916–1920 was 503 and the rate 4.9 p 100,000 population.

Measles. The deaths ascribed to measles in 1921 were 412 number, corresponding to a mortality of 3.9 per 100,000 populati This is considerably lower than the rate for 1920, which was 10 with a total of 1,101 deaths. The annual average rate for 191 1920 was 8.9 with 914 deaths.

Scarlet fever caused 666 deaths this year, the mortality bei 6.3 per 100,000 population,— an increase over 1920 of 216 deat in number and of 2.0 points in rate. Compared with the ann average number and rate of 1916–1920, there was an increase 1921 of 376 deaths and 3.5 points in rate.

Whooping cough in 1921 caused 756 deaths, the mortality bei 7.2 per 100,000 population; the rate for 1920 was 9.6 with 1,0 deaths and the 1916–1920 average was 8.2 with 836 deaths.

Diphtheria caused 1,702 deaths this year with a mortality r of 16.1 per 100,000 population. This is below the 1920 rate, whi was 18.2 with 1,904 deaths and the annual average for 1916–19 which was 17.6 with 1,803 deaths.

Cerebrospinal meningitis. The deaths classified to this headi during 1921 numbered 249, corresponding to a rate of 2.4 p 100,000 population. This shows an increase over 1920 of 59 deat and 0.6 in rate. The annual average number for 1916–1920 w 307 with a rate of 3.0.

Acute anterior poliomyelitis (infantile paralysis) was the ca of 266 deaths in 1921, corresponding to a mortality of 2.5 p 100,000 population. There was an extensive prevalence of pol myelitis throughout the State during the summer and fall and m cases were reported in 1921 than in any year on record, exce 1916 and 1912. During the great epidemic of 1916 there occurr 3,351 deaths from this cause.

	Deaths	Rate per 100,000 population
17 (annual average)	737	7.5
	57	0.6
	35	0.3
	50	0.5
	266	2.5

nza caused 778 deaths this year, corresponding to a mor- 7.4 per 100,000 population. In 1920 there were 5,890 rom this disease, there being a slight recurrence of the in February of that year. The very mild winter of 1921 accounts for the low mortality from this cause this year.

	Deaths	Rate per 100,000 population
7 (annual average)	1,534	15.7
	26,502	259.1
	8,047	77.9
	5,890	56.4
	778	7.4

nary tuberculosis, including acute miliary, caused 9,407 the State this year — a rate of 89.2 per 100,000 popula- e number of deaths from this disease has decreased extra- y during the last few years, as shown in the following n:

	Deaths	Rate per 100,000 population
7 (annual average)	14,412	147.1
	15,052	147.2
	12,814	124.0
	11,030	105.7
	9,407	89.2

ulous meningitis has also decreased from an average of 100,000 population in 1913–1917 to 8.9 in 1919, 7.8 in 6.0 in 1921.

end of *all forms of tuberculosis* is shown by the following:

	Deaths	Rate per 100,000 population
7 (annual average)	16,322	166.6
	16,973	166.0
	14,478	140.1
	12,543	120.2
	10,775	102.2

The United States Bureau of the Census has adjusted the rates from tuberculosis for age and sex for the various subdivisions of the Registration Area. The 1921 rate for New York State when adjusted becomes 96.3. Among the 34 states of the Registration Area, New York State stands thirteenth on the list of adjusted rates. Of course, the rate for New York State should also be adjusted for residents and nonresidents, as the very excellent health resorts attract many people from outside the State.

Cancer (all forms combined) caused 11,163 deaths in 1921, corresponding to a rate of 105.9 per 100,000 population. This mortality has been increasing steadily:

Year	Deaths	Rate per 100,000 population
1913–1917 (annual average)	9,180	93.7
1918	9,876	96.6
1919	10,166	98.4
1920	10,539	101.0
1921	11,163	105.9

The 1921 rate when adjusted for age and sex (by the U. S. Census) becomes 96.0. The unadjusted rate for the U. S. Registration Area in 1921 was 86.0.

Diabetes which caused 2,220 deaths in 1921, corresponding to a rate of 21.1 per 100,000 population, shows but little change during a period of years:

Year	Deaths	Rate per 100,000 population
1913–1917 (annual average)	2,067	21.1
1918	2,076	20.3
1919	1,972	19.1
1920	2,188	21.0
1921	2,220	21.1

The rate for 1921 when adjusted (by the U. S. Census) for age and sex becomes 21.8, this being the highest adjusted rate for any State in the Registration Area. The unadjusted rate for the Registration Area was but 16.8 in 1921.

Cerebral hemorrhage and apoplexy (combined) caused 7,148 deaths in 1921, an increase of 296 deaths over 1920. This mortality has shown a slight upward trend since 1909.

Year	Deaths	Rate per 100,000 population
1913–1917 (annual average)	6,436	65.7
1918	7,019	68.6
1919	6,638	64.2
1920	6,852	65.6
1921	7,148	67.8

Organic heart disease and endocarditis (combined) caused more deaths in 1921 than any other cause of death,— 23,090 in number with a rate of 219.0 per 100,000 population,— an increase of 433 deaths over 1920. The mortality from this cause showed a continuous increase from 1908–1918. There was a marked drop in 1919, but the disease appears to have again resumed its normal increase:

Year	Deaths	Rate per 100,000 population
1913–1917 (annual average)	20,581	210.1
918	23,456	229.4
919	20,644	199.8
920	22,657	217.1
21	23,090	219.0

Arteriosclerosis in 1921 was the cause of 4,655 deaths, the rate 100,000 population being 44.2 The mortality from this cause shown a tendency to increase within recent years:

ar	Deaths	Rate per 100,000 population
3–1917 (annual average)	4,402	44.9
	4,616	45.1
	4,685	45.3
	4,883	46.8
	4,655	44.2

nchitis (acute and chronic combined) which caused 1,145 in 1921 has been decreasing of late years. There were 614 deaths in 1921 than in 1920.

	Deaths	Rate per 100,000 population
917 (annual average)	1,808	18.5
	1,839	18.0
	1,497	14.5
	1,759	16.9
	1,145	10.9

onia. The total deaths assigned to pneumonia (all forms) 10,645 in 1921, corresponding to a mortality of 101.0 0 population. This disease showed a remarkable decrease from 1920 when the rate was 157.8. This decrease occurr in bronchopneumonia and in lobar, as will be seen from lowing table:

YEAR	LOBAR PNEUMONIA AND UNQUALIFIED		BRONCHO-PNEUMONIA		ALL COM
	Deaths	Rate	Deaths	Rate	Deaths
1913–1917 (annual average)	10,108	103.2	6,939	70.8	17,047
1918	23,949	234.2	10,564	103.3	34,513
1919	9,712	94.0	7,384	71.5	17,096
1920	8,907	85.3	7,568	72.5	16,475
1921	5,866	55.6	4,779	45.4	10,645

Appendicitis caused 1,468 deaths in 1921, an increase deaths over 1920 and of 249 over the annual average of 191

Hernia and intestinal obstruction. There were reporte deaths from this cause in 1921, represented by a mortality per 100,000 population. This cause shows very little chan year to year, viz.:

Year	Deaths
1913–1917 (annual average)	1,227
1918	1,317
1919	1,222
1920	1,214
1921	1,226

Cirrhosis of the liver caused 729 deaths in 1921, a dec 50 deaths over 1920. The number of deaths allocated to t has been decreasing rapidly in recent years.

Year	Deaths
1913–1917 (annual average)	1,438
1918	998
1919	842
1920	779
1921	729

Nephritis and Bright's disease (acute and chronic disease) caused 9,481 deaths in 1921 and ranks fifth am leading causes of death. This death rate varied but little d long course of years; from 1900–1917 the death rate flu ween 112.6 and 132.9. It declined sharply in 1918, again in 9, slightly in 1920, and considerably in 1921, as seen by the e below:

ar	Deaths	Rate per 100,000 population
3–1917 (annual average)	12,113	123.7
8	11,315	110.6
9	10,540	102.0
0	10,481	100.4
1	9,481	89.9

uerperal causes. The number of deaths assigned to pregcy and childbirth was 1,396 in 1921, a decrease of 28 deaths 1920. The death rate from this cause has remained practiy stationary for the last ten years:

ar	Deaths	Rate per 100,000 population
3–1917 (annual average)	1,306	13.3
8	1,563	15.3
9	1,274	12.3
)	1,424	13.6
1	1,396	13.2

uerperal septicemia caused 412 deaths, or 30 per cent of the 6 deaths from all puerperal causes. This death rate has shown ndency to decrease within the last ten years, but there were 28 e deaths from this cause in 1921 than in 1920.

ar	Deaths	Rate per 100,000 population
3–1917 (annual average)	470	4.8
3	410	4.0
9	352	3.4
)	384	3.7
1	412	3.9

ince the better measure for mortality from these causes would rate based upon the number of births (live and still) reported year, such a table is given below with the rates on this basis New York State, New York City, and the Rest of State:

Deaths and Death Rates from all Puerperal Causes

YEAR	New York State		New York City		Rest of Stat	
	Number of deaths	Rate per 10,000 births (including stillbirths)	Number of deaths	Rate per 10,000 births (including stillbirths)	Number of deaths	Rate p 10,00 birth (includ stillbirt
1915	1,323	52.20	709	48.0	614	5
1916	1,231	49.06	657	45.8	574	5
1917	1,333	52.00	651	44.1	682	6
1918	1,563	61.63	664	45.8	899	8
1919	1,274	54.05	644	47.2	630	6
1920	1,424	57.97	708	50.9	716	6
1921	1,396	55.74	746	53.1	650	5

Old age, to which 708 deaths were allocated in 1921, showed rate of 6.7 per 100,000 population. This title may be regarded an index of the accuracy of statements as to the causes of death aged people, and as such it indicates constant improvement certification during recent years, viz.:

Year	Deaths	Rate p 100,00 populat
1913–1917 (annual average)	1,208	12
1918	826	8
1919	873	8
1920	838	8
1921	708	6

Accidents (all external causes except suicide and homicide) r sulted in 7,187 deaths in 1921, the rate per 100,000 populati being 68.2. During recent years a slight decrease in this rate w be noticed. The fact that accidents cause over 7,000 deaths a ye makes it one of the major causes of death,— in fact, in 1921 ranks sixth in importance:

Year	Deaths	Rate p 100,00 populat
1913–1917 (annual average)	8,112	82
1918	8,448	82
1919	7,433	71
1920	7,351	70
1921	7,187	68

tomobile accidents, which caused 1,629 deaths in 1921, are ily increasing in importance relative to other causes of death,

r	Deaths	Rate per 100,000 population
-1917 (annual average)................	608	6.2
....	1,216	11.9
....	1,361	13.2
....	1,439	13.8
....	1,629	15.5

cidental drowning showed a very marked increase over 1920, being 869 deaths from this cause alone compared with 726 in :

r	Deaths	Rate per 100,000 population
-1917 (annual average)................	1,042	10.6
....	909	8.9
....	869	8.4
....	726	7.0
....	869	8.2

icide showed a rate of 13.7 for this year which is the highest since 1917. There were 1,442 deaths in 1921,— 253 more than 20:

	Deaths	Rate per 100,000 population
-1917 (annual average)................	1,521	15.5
....	1,302	12.7
....	1,294	12.5
....	1,189	11.4
....	1,442	13.7

micide resulted in 501 deaths in 1921,— 53 more than in This rate has shown a tendency to increase in recent years, dicated in the table below:

	Deaths	Rate per 100,000 population
-1917 (annual average)................	425	4.3
....	385	3.8
....	430	4.2
....	448	4.3
....	501	4.8

Joint Causes of Death

For the year 1921 a special table has been prepared showing the contributory causes of death in relation to the primary causes for all the deaths occurring in the State outside of New York City. The table is too large to be published in detail in this report, but a summary follows. Of the 65,853 deaths recorded there were 26,469, or 40 per cent, where more than one disease was given as the cause of death.

The table is to be read as follows: There were 254 deaths assigned to typhoid fever as the preferred cause of death; there were 3 other deaths (in addition to the 254) where typhoid fever was given as the contributory cause; of the 254 typhoid deaths, 107 of them had some other disease or condition given as a contributory cause.

Some of the outstanding features of the table are as follows:

> Of the 247 deaths from measles, only 45 were returned as having no complications.
>
> Septicemia and purulent infection had 96 deaths charged to it, while there were 268 other deaths where septicemia contributed to the death.
>
> There were 61 deaths allocated to alcoholism while in addition, there were 55 deaths where alcoholism was a contributory cause.
>
> Meningitis is credited with 208 deaths, but there were 314 other deaths which were complicated with meningitis.
>
> Diseases of the arteries, credited with 1,956 deaths, shows 4,831 other deaths where diseases of the arteries was a contributory cause.
>
> In addition to the 650 deaths from puerperal causes, there were 94 deaths assigned to other causes where the puerperal condition was present.

From the detailed table (not published in this report) the following facts are of interest:

> Of the 247 deaths from measles, 158 were complicated with pneumonia.
>
> Of 1,100 deaths from diabetes, 177 were complicated with diseases of the cardiovascular system and 88 with nephritis and Bright's disease.
>
> Of 6,262 deaths from cerebral hemorrhage and apoplexy, 2,026 were complicated with arteriosclerosis, 358 with nephritis and Bright's disease, and 247 with senility.
>
> Of 4,168 deaths from pneumonia (all forms), 323 were complicated with organic heart disease, 157 with arteriosclerosis, and 141 with senility.
>
> Of the 1,965 deaths from diarrhea and enteritis (under 2 years), 17 were complicated with whooping cough, 36 with simple meningitis, 107 with infantile convulsions, 42 with bronchitis, 70 with pneumonia, and 42 with premature birth or injury at birth.

Of the 5,376 deaths from acute nephritis and Bright's disease, 12 were with influenza, 21 with anemia, 7 with alcoholism, 181 with cerebral hemorrhage and apoplexy, 1,316 with organic heart disease, 543 with arteriosclerosis, 79 with pneumonia, and 125 with senility.

There are other interesting and important facts to be noted in his table, too numerous to be mentioned here. However, this rief summary gives an insight into the classification of the joint auses of death.

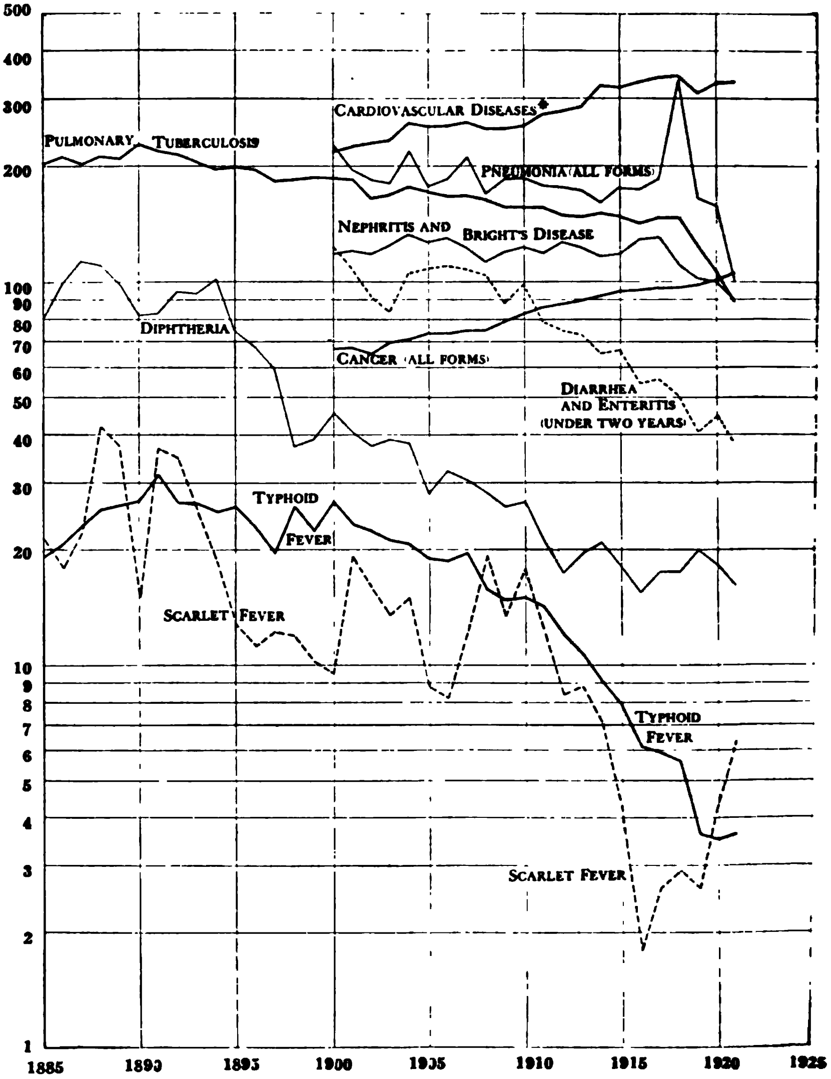
and deaths per 1,000 population; deaths under 1 year per 1,000 living births (infant leaths for all other ages and by causes per 100,000 population.

stimated on the basis of the increase between the U. S. censuses of 1910 and 1920 (comhmetic method) for New York City and the State Enumeration of 1915 and the United 1920 for the rest of State.

rs to the left of each title are those of the International List of Causes of Death (Revision

acute miliary tuberculosis (37c) for New York City not included — not available.

MOVEMENT OF DEATH RATES FOR 100,000 POPULATION FROM IMPORTANT CAUSES, ENTIRE STATE OF NEW YORK



---

* This title includes Cerebral Hemorrhage, Apoplexy, Organic heart disease, Endocarditis, and Arteriosclerosis.

STATISTICAL TABLES

NG AND ANALYZING THE RESULTS OF REGISTRATION OF , DEATHS AND MARRIAGES IN THE STATE OF NEW YORK TS SUBDIVISIONS DURING THE YEAR 1921, WITH COM- VE DATA FOR PREVIOUS YEARS*

---

to 1914 the original certificates of births and deaths were not filed
State Department of Health from the cities of New York, Albany,
d Yonkers, the data for those cities included in the reports of the
rtment being based upon the compilations prepared monthly by
tive local registers of these cities.

g January 1, 1914, the State Department of Health has been
he original certificates of births and deaths from all cities, towns
es in the State, excepting only New York City. Unless otherwise
therefore, the compilations presented in the monthly bulletins and
orts of the Department since 1914 are based upon the data given
ginal certificates, except for New York City, the figures for which
ed monthly by the Registrar of Records of the New York City
t of Health.

---

[1] Population estimates are based upon the average annual increase or decrease between the United States Censuses of 1910 and 1920 for New York City, and upon the State Enumeration of 1915 and United States Census of 1920 for the rest of State.

[2] Civilian deaths only, except for New York City.

[3] Includes cities and three large villages listed.

[4] "Rural" as used in this table includes all of New York State, exclusive of New York City and the cities and three large villages listed, and institutional districts.

[5] Exclusive of populations and deaths in institutional districts.

[6] Special charter.

[1] Population estimates are based upon the average annual increase or decrease between the United States Censuses of 1910 and 1920 for New York City, and upon the State Enumeration of 1915 and United States Census of 1920 for the rest of State.

[2] Civilian deaths only, except for New York City.

[3] Includes cities and three large villages listed.

[4] "Rural" as used in this table includes all of New York state, exclusive of New York City and the cities and three large villages listed, and institutional districts.

[5] Exclusive of populations and deaths in institutional districts.

[6] Special charter.
